As the term suggests, network policy refers to the network-wide controls you can implement to:

- Ensure uniform and efficient traffic handling throughout your network, while keeping the most important traffic moving at an acceptable speed, regardless of current bandwidth usage.
- Exercise control over the priority settings of inbound traffic arriving in and travelling through your network.

Adding bandwidth is often a good idea, but it is not always feasible and does not completely eliminate the potential for network congestion. There will always be points in the network where multiple traffic streams merge or where network links will change speed and capacity. The impact and number of these congestion points will increase over time as more applications and devices are added to the network.

When (not if) network congestion occurs, it is important to move traffic on the basis of relative importance. However, without Quality of Service (QoS) prioritization, less important traffic can consume network bandwidth and slow down or halt the delivery of more important traffic. That is, without QoS, most traffic received by the switch is forwarded with the same priority it had upon entering the switch. In many cases, such traffic is “normal” priority and competes for bandwidth with all other normal-priority traffic, regardless of its relative importance to your organization’s mission.

This section gives an overview of QoS operation and benefits, and describes how to configure QoS in the console interface.
Quality of Service (QoS): Managing Bandwidth More Effectively

Introduction

Quality of Service is a general term for classifying and prioritizing traffic throughout a network. That is, QoS enables you to establish an end-to-end traffic priority policy to improve control and throughput of important data. You can manage available bandwidth so that the most important traffic goes first. For example, you can use Quality of Service to:

- Upgrade or downgrade traffic from various servers.
- Control the priority of traffic from dedicated VLANs or applications.
- Change the priorities of traffic from various segments of your network as your business needs change.
- Set priority policies in edge switches in your network to enable traffic-handling rules across the network.

**Figure 8-1. Example of 802.1p Priority Based on CoS (Class-of-Service) Types and Use of VLAN Tags**

**Figure 8-2. Example Application of Differentiated Services Codepoint (DSCP) Policies**

At the edge switch, QoS classifies certain traffic types and in some cases applies a DSCP policy. At the next hop (downstream switch) QoS honors the policies established at the edge switch. Further downstream, another switch may reclassify some traffic by applying new policies, and yet other downstream switches can be configured to honor the new policies.
QoS is implemented in the form of rules or policies that are configured on the switch. While you can use QoS to prioritize only the outbound traffic while it is moving through the switch, you derive the maximum benefit by using QoS in an 802.1Q VLAN environment (with 802.1p priority tags) or in an untagged VLAN environment (with DSCP policies) where QoS can set priorities that downstream devices can support without re-classifying the traffic.

By prioritizing traffic, QoS supports traffic growth on the network while optimizing the use of existing resources—and delaying the need for further investments in equipment and services. That is, QoS enables you to:

- Specify which traffic has higher or lower priority, regardless of current network bandwidth or the relative priority setting of the traffic when it is received on the switch.
- Change (upgrade or downgrade) the priority of outbound traffic.
- Override “illegal” packet priorities set by upstream devices or applications that use 802.1Q VLAN tagging with 802.1p priority tags.
- Avoid or delay the need to add higher-cost NICs (network interface cards) to implement prioritizing. (Instead, control priority through network policy.)

QoS on the switches covered by this guide supports these types of traffic marking:

- **802.1p prioritization**: Controls the outbound port queue priority for traffic leaving the switch, and (if traffic exits through a VLAN-tagged port) sends the priority setting with the individual packets to the downstream devices.

- **IP Type-of-Service (ToS)**: Enables the switch to set, change, and honor prioritization policies by using the Differentiated Services (difserv) bits in the ToS byte of IPv4 packet headers.
Terminology

<table>
<thead>
<tr>
<th>Term</th>
<th>Use in This Document</th>
</tr>
</thead>
<tbody>
<tr>
<td>802.1p priority</td>
<td>A traffic priority setting carried by a VLAN-tagged packet moving from one device to another through ports that are tagged members of the VLAN to which the packet belongs. This setting can be from 0-7. The switch handles an outbound packet on the basis of its 802.1p priority. However, if the packet leaves the switch through a VLAN on which the port is an untagged member, this priority is dropped, and the packet arrives at the next, downstream device without an 802.1p priority assignment.</td>
</tr>
<tr>
<td>802.1Q field</td>
<td>A four-byte field that is present in the header of Ethernet packets entering or leaving the switch through a port that is a tagged member of a VLAN. This field includes an 802.1p priority setting, a VLAN tag, or ID number (VID), and other data. A packet entering or leaving the switch through a port that is an untagged member of the outbound VLAN does not have this field in its header and thus does not carry a VID or an 802.1p priority. See also “802.1p priority”.</td>
</tr>
<tr>
<td>codepoint</td>
<td>Refer to DSCP, below.</td>
</tr>
<tr>
<td>downstream device</td>
<td>A device linked directly or indirectly to an outbound switch port. That is, the switch sends traffic to downstream devices.</td>
</tr>
<tr>
<td>DSCP</td>
<td>Differentiated Services Codepoint. (Also termed codepoint.) A DSCP is comprised of the upper six bits of the ToS (Type-of-Service) byte in IP packets. There are 64 possible codepoints. In the default QoS configuration for the 5300x1 switches, some codepoints are configured with default 802.1p priority settings for Assured-Forwarding and Expedited Forwarding. In the default QoS configuration for the 3400cl/6400cl switches, one codepoint (101110) is set for Expedited Forwarding. All other codepoints are unused (and listed with No-override for a priority).</td>
</tr>
<tr>
<td>DSCP policy</td>
<td>A DSCP configured with a specific 802.1p priority (0-7). (Default: No-override). Using a DSCP policy, you can configure the switch to assign priority to IP packets. That is, for an IP packet identified by the specified classifier, you can assign a new DSCP and an 802.1p priority (0-7). For more on DSCP, refer to “Details of QoS IP Type-of-Service” on page 8-47. For the DSCP map, see figure 8-23 on page 8-48.</td>
</tr>
<tr>
<td>edge switch</td>
<td>In the QoS context, this is a switch that receives traffic from the edge of the LAN or from outside the LAN and forwards it to devices within the LAN. Typically, an edge switch is used with QoS to recognize packets based on classifiers such as TCP/UDP application type, IP-device (address), Protocol (LAN), VLAN-ID (VID), and Source-Port (although it can also be used to recognize packets on the basis of ToS bits). Using this packet recognition, the edge switch can be used to set 802.1p priorities or DSCP policies that downstream devices will honor.</td>
</tr>
<tr>
<td>inbound port</td>
<td>Any port on the switch through which traffic enters the switch.</td>
</tr>
<tr>
<td>IP Options</td>
<td>In an IPv4 packet, optional, these are extra fields in the packet header.</td>
</tr>
<tr>
<td>IP-precedence bits</td>
<td>The upper three bits in the Type of Service (ToS) field of an IP packet.</td>
</tr>
<tr>
<td>IPv4</td>
<td>Version 4 of the IP protocol.</td>
</tr>
<tr>
<td>outbound packet</td>
<td>A packet leaving the switch through any LAN port.</td>
</tr>
<tr>
<td>outbound port</td>
<td>Any port on the switch through which traffic leaves the switch.</td>
</tr>
</tbody>
</table>
Overview

QoS settings operate on two levels:

- **Controlling the priority of outbound packets moving through the switch:** Each switch port has four outbound traffic queues; “low”, “normal”, “medium”, and “high” priority. Packets leave the switch port on the basis of their queue assignment and whether any higher queues are empty.

Table 8-1. Port Queue Exit Priorities

<table>
<thead>
<tr>
<th>Port Queue and 802.1p Priority Values</th>
<th>Priority for Exiting From the Port</th>
</tr>
</thead>
<tbody>
<tr>
<td>Low (1 - 2)</td>
<td>Fourth</td>
</tr>
<tr>
<td>Normal (0, 3)</td>
<td>Third</td>
</tr>
<tr>
<td>Medium (4 - 5)</td>
<td>Second</td>
</tr>
<tr>
<td>High (6 - 7)</td>
<td>First</td>
</tr>
</tbody>
</table>

A QoS configuration enables you to set the outbound priority queue to which a packet is sent. (In an 802.1Q VLAN environment with VLAN-tagged ports, if QoS is not configured on the switch, but is configured on an upstream device, the priorities carried in the packets determine the forwarding queues in the switch.)
■ Configuring a priority for outbound packets and a service (priority) policy for use by downstream devices:

- **DSCP Policy:** This feature enables you to set a priority policy in outbound IP packets. (You can configure downstream devices to read and use this policy.) This method is not dependent on VLAN-tagged ports to carry priority policy to downstream devices, and can:
  - Change the codepoint (the upper six bits) in the ToS byte.
  - Set a new 802.1p priority for the packet.

  (Setting DSCP policies requires IPv4 inbound packets. Refer to the “IPv4” entry under “Terminology” on page 8-6.)

- **802.1p Priority Rules:** An outbound, VLAN-tagged packet carries an 802.1p priority setting that was configured (or preserved) in the switch. This priority setting ranges from 0 to 7, and can be used by downstream devices having up to eight outbound port queues. Thus, while packets within the switch move at the four priority levels shown in table 8-1, above, they still can carry an 802.1p priority that can be used by downstream devices having more or less than the four priority levels in the switches covered by this guide. Also, if the packet enters the switch with an 802.1p priority setting, QoS can override this setting if configured with an 802.1p priority rule to do so.

**Notes:**

If your network uses only one VLAN (and therefore does not require VLAN-tagged ports) you can still preserve 802.1p priority settings in your traffic by configuring the ports as tagged VLAN members on the links between devices you want to honor traffic priorities.

**Rule and Policy Limits:** The switches covered by this guide have differing limits on the number of rules and policies they support:

- **5300xl Switches and 4200vl Switches:** Beginning with software release **E.08.01**, the switch allows up to **250** 802.1p priority rules and/or DSCP policies in any combination. For more information, refer to “Maximum QoS Configuration Entries” under “QoS Operating Notes and Restrictions” on page 8-73.

- **3400cl/6400cl Switches:** The combined number of 802.1p priority rules and DSCP policies the switch supports depends on the usage of rules by the ACL and other factions. Refer to “QoS Operating Notes and Restrictions” on page 8-73.
You can configure a QoS priority of 0 through 7 for an outbound packet. When the packet is then sent to a port, the QoS priority determines which outbound queue the packet uses:

**Table 8-2. QoS Priority Settings and Operation**

<table>
<thead>
<tr>
<th>QoS Priority Setting</th>
<th>Outbound Port Queue</th>
</tr>
</thead>
<tbody>
<tr>
<td>1 - 2</td>
<td>low priority</td>
</tr>
<tr>
<td>0 - 3</td>
<td>normal priority</td>
</tr>
<tr>
<td>4 - 5</td>
<td>medium priority</td>
</tr>
<tr>
<td>6 - 7</td>
<td>high priority</td>
</tr>
</tbody>
</table>

If a packet is not in a VLAN-tagged port environment, then the QoS settings in table 8-2 control only to which outbound queue the packet goes. Without VLAN tagging, no 802.1p priority is added to the packet for downstream device use. But if the packet is in a VLAN-tagged environment, then the above setting is also added to the packet as an 802.1p priority for use by downstream devices and applications (shown in table 8-3). In either case, an IP packet can also carry a priority policy to downstream devices by using DSCP-marking in the ToS byte.

Classifiers for Prioritizing Outbound Packets

The classifiers used in the 3400cl/6400cl switches are a subset of the classifiers used in the 5300xl and 4200vl switches. Also, the 3400cl/6400cl switches search for classifier matches in the opposite order of that used in the 5300xl and 4200vl switches.

HP recommends that you configure a minimum number of the available QoS classifiers for prioritizing any given packet type. Increasing the number of active classifier options for a packet type increases the complexity of the possible outcomes and consumes switch resources.

5300xl and 4200vl Packet Classifiers and Evaluation Order

The 5300xl and 4200vl switches provide seven QoS classifiers (packet criteria) you can use to configure QoS priority.

Table 8-4. 5300xl and 4200vl Classifier Search Order and Precedence

<table>
<thead>
<tr>
<th>Search Order</th>
<th>Precedence</th>
<th>QoS Classifier Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>1 (highest)</td>
<td>UDP/TCP Application Type (port)</td>
</tr>
<tr>
<td>2</td>
<td>2</td>
<td>Device Priority (destination or source IP address)</td>
</tr>
<tr>
<td>3</td>
<td>3</td>
<td>IP Type of Service (ToS) field (IP packets only)</td>
</tr>
<tr>
<td>4</td>
<td>4</td>
<td>Protocol Priority (IP, IPX, ARP, DEC LAT, AppleTalk, SNA, and NetBeui)</td>
</tr>
<tr>
<td>5</td>
<td>5</td>
<td>VLAN Priority</td>
</tr>
<tr>
<td>6</td>
<td>6</td>
<td>Incoming source-port on the switch</td>
</tr>
<tr>
<td>7</td>
<td>7 (lowest)</td>
<td>Incoming 802.1p Priority (present in tagged VLAN environments)</td>
</tr>
</tbody>
</table>

Where multiple classifier types are configured, a 5300xl or 4200vl switch uses the highest-to-lowest search order shown in table 8-4 to identify the highest-precedence classifier to apply to any given packet. When a match between a packet and a classifier is found, the switch applies the QoS policy configured for that classifier and the packet is handled accordingly.

Note that on a 5300xl or 4200vl switch, if the switch is configured with multiple classifiers that address the same packet, the switch uses only the QoS configuration for the QoS classifier that has the highest precedence. (In this case, the QoS configuration for another, lower-precedence classifier that may apply is ignored.) For example, if QoS assigns high priority to packets belonging to VLAN 100, but normal priority to all IP protocol packets, since protocol priority (4) has precedence over VLAN priority (5), IP protocol packets on VLAN 100 will be set to normal priority.
3400cl/6400cl Packet Classifiers and Evaluation Order

The 3400cl/6400cl switches provide six QoS classifiers (packet criteria) you can use to configure QoS priority.

**Table 8-5. 3400cl/6400cl Classifier Search Order and Precedence**

<table>
<thead>
<tr>
<th>Search Order</th>
<th>Precedence</th>
<th>QoS Classifier</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>6 (lowest)</td>
<td>Incoming 802.1p Priority (present in tagged VLAN environments)</td>
</tr>
<tr>
<td>2</td>
<td>5</td>
<td>Incoming source-port on the switch</td>
</tr>
<tr>
<td>3</td>
<td>4</td>
<td>VLAN Priority</td>
</tr>
<tr>
<td>4</td>
<td>3</td>
<td>IP Type of Service (ToS) field (IP packets only)</td>
</tr>
<tr>
<td>5</td>
<td>2</td>
<td>Device Priority (destination or source IP address)</td>
</tr>
<tr>
<td>6</td>
<td>1 (highest)</td>
<td>UDP/TCP Application Type (port)</td>
</tr>
</tbody>
</table>

A 3400cl or 6400cl switch uses the lowest-to-highest search order shown in table 8-5 to identify the highest-precedence classifier to apply to any given packet. (Note that this is the opposite of the order used in the 5300xl or 4200vl switches.) If there is only one configured classifier that matches a given packet, then the switch applies the QoS policy specified in that classifier. If multiple configured classifiers match a given packet, the switch applies each one in turn to the packet and concludes with the QoS policy for the highest-precedence classifier. Note that if the highest precedence classifier is configured to apply a DSCP policy, then both the DSCP in the packet and the 802.1p priority applied to the packet can be changed. However, if the highest precedence classifier is configured to apply an 802.1p priority rule, only the 802.1p priority in the final QoS match for the packet is changed.

---

**Note**

On the 3400cl/6400cl switches, intermixing lower-precedence classifiers configured with DSCP policies and higher-precedence classifiers configured with 802.1p priority rules is not recommended, as this can result in a packet with an 802.1p priority assigned by one classifier and a DSCP policy by another classifier. This is because the search order would allow a lower precedence classifier configured with a DSCP policy to change both the DSCP and the 802.1p setting in a packet, and then would allow a subsequent, higher precedence classifier configured with an 802.1p priority rule to change only the 802.1p setting. To avoid this problem, a DSCP policy option should be applied only on the highest-precedence classifier in use on the switch or applied to all QoS classifiers in use on the switch.
In general, the precedence of QoS classifiers should be considered when configuring QoS policies. For example, suppose that a system administrator has used an 802.1p priority rule to assign a high priority for packets received on VLAN 100, but has also used another 802.1p priority rule to assign a normal priority for TCP port 80 packets received on the switch. Since TCP/UDP port precedence supersedes VLAN precedence, all TCP port 80 packets on VLAN 100 will be set to normal priority. For a classifier precedence listing, see table 8-5, “3400cl/6400cl Classifier Search Order and Precedence”, on page 8-11.

Table 8-6. Precedence Criteria for QoS Classifiers

<table>
<thead>
<tr>
<th>Precedence</th>
<th>Criteria</th>
<th>Overview</th>
</tr>

## Precedence Criteria Overview

<table>
<thead>
<tr>
<th>Precedence</th>
<th>Criteria</th>
<th>Overview</th>
</tr>
</thead>
<tbody>
<tr>
<td>4</td>
<td>Layer 3 Protocol Priority</td>
<td><strong>Note:</strong> This classifier is available in the 5300xl and 4200vl switches, but not in the 3400cl/6400cl switches. To prioritize traffic in a 3400cl or 6400cl switch according to protocol type, configure the switch to place traffic of the desired protocol type in a specific VLAN, and then apply the VLAN classifier. Takes precedence based on network protocols: IP, IPX, ARP, DEC LAT, AppleTalk, SNA, and NetBeui. <strong>Default state:</strong> No-override for any protocol. If a packet does not meet the criteria for Protocol priority, then precedence defaults to the VLAN classifier, below.</td>
</tr>
<tr>
<td>5</td>
<td>VLAN Priority</td>
<td>Takes precedence based on the ID number of the VLAN in which the inbound packet exists. For example, if the default VLAN (VID = 1) and the “Blue” VLAN (with a VID of 20) are both assigned to a port, and Blue VLAN traffic is more important, you can configure QoS to give Blue VLAN traffic a higher priority than default VLAN traffic. (Priority is applied on the outbound port.) <strong>Default state:</strong> No-override. If a packet does not meet the criteria for VLAN priority, then precedence defaults to the Source-Port classifier, below.</td>
</tr>
<tr>
<td>6</td>
<td>Source-Port</td>
<td>Takes precedence based on the source-port (that is, the port on which the packet entered the switch). If a packet does not meet the criteria for source-port priority, then precedence defaults to Incoming 802.1p criteria, below.</td>
</tr>
<tr>
<td>7</td>
<td>Incoming 802.1p Priority</td>
<td>Where a VLAN-tagged packet enters the switch through a port that is a tagged member of that VLAN, if QoS is not configured to override the packet’s priority setting, the switch uses the packet’s existing 802.1p priority (assigned by an upstream device or application) to determine which inbound and outbound port queue to use. If there is no QoS policy match on the packet, and it then leaves the switch through a port that is a tagged member of the VLAN, then there is no change to its 802.1p priority setting. If the packet leaves the switch through a port that is an untagged member of the VLAN, the 802.1p priority is dropped.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Entering (Inbound) 802.1p Priority</th>
<th>Outbound Port Queue</th>
<th>Exiting (Outbound) 802.1p Priority</th>
</tr>
</thead>
<tbody>
<tr>
<td>1 - 2</td>
<td>Low</td>
<td>1 - 2</td>
</tr>
<tr>
<td>0 - 3</td>
<td>Normal</td>
<td>0 - 3</td>
</tr>
<tr>
<td>4 - 5</td>
<td>Medium</td>
<td>4 - 5</td>
</tr>
<tr>
<td>6 - 7</td>
<td>High</td>
<td>6 - 7</td>
</tr>
</tbody>
</table>

If a packet does not meet the criteria for Incoming 802.1p priority, then the packet goes to the “normal” outbound queue of the appropriate port. If the packet entered the switch through a port that is an untagged member of a VLAN, but exits through a VLAN-tagged port, then an 802.1Q field, including an 802.1p priority, is added to the packet header. If no QoS policy is configured or applied to the packet, then the 802.1p priority of 0 (normal) is assigned to the packet for outbound transmission.
Preparation for Configuring QoS

QoS operates in VLAN-tagged and VLAN-untagged environments. If your network does not use multiple VLANs, you can still implement the 802.1Q VLAN capability for packets to carry their 802.1p priority to the next downstream device. To do so, configure ports as VLAN-tagged members on the links between switches and routers in your network infrastructure.

</tbody>
</table>

¹ Except for non-IPv4 packets or packets processed using either the Layer 3 Protocol (5300xl and 4200vl only) or QoS IP-Precedence methods, which do not include the DSCP policy option. Also, to use a service policy in this manner, the downstream devices must be configured to interpret and use the DSCP carried in the IP packets.

² This priority corresponds to the 802.1p priority scheme and is used to determine the packet's port queue priority. When used in a VLAN-tagged environment, this priority is also assigned as the 802.1p priority carried outbound in packets having an 802.1Q field in the header.

Steps for Configuring QoS on the Switch

1. Determine the QoS policy you want to implement. This includes analyzing the types of traffic flowing through your network and identifying one or more traffic types to prioritize. In order of QoS precedence, these are:
   a. UDP/TCP applications
   b. Device Priority—destination or source IP address (Note that destination has precedence over source. See Table 8-6.)
   c. IP Type-of-Service Precedence Bits (Leftmost three bits in the ToS field of IP packets)
   d. IP Type-of-Service Differentiated Service bits (Leftmost six bits in the ToS field of IP packets)
   e. Protocol Priority (Series 5300xl switches only)
   f. VLAN Priority (requires at least one tagged VLAN on the network)
   g. Source-Port
h. Incoming 802.1p Priority (requires at least one tagged VLAN on the network)

For more on how QoS operates with the preceding traffic types, see “Precedence Criteria for QoS Classifiers”, on page 8-12.)

Select the QoS option you want to use. Table 8-8 lists the traffic types (QoS classifiers) and the QoS options you can use for prioritizing or setting a policy on these traffic types:

Table 8-8. Applying QoS Options to Traffic Types Defined by QoS Classifiers

<table>
<thead>
<tr>
<th>QoS Options for Prioritizing Outbound Traffic</th>
<th>QoS Classifiers</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>UDP/ TCP</td>
</tr>
<tr>
<td><strong>Option 1: Configure 802.1p Priority Rules Only</strong></td>
<td></td>
</tr>
<tr>
<td>Prioritize traffic by sending specific packet types (determined by QoS classifier) to different outbound port queues on the switch.</td>
<td>Yes</td>
</tr>
<tr>
<td>Rely on VLAN-tagged ports to carry packet priority as an 802.1p value to downstream devices.</td>
<td></td>
</tr>
<tr>
<td><strong>Option 2: Configure ToS DSCP Policies with 802.1p Priorities</strong></td>
<td></td>
</tr>
<tr>
<td>Prioritize traffic by sending specific packet types (determined by QoS classifier) to different outbound port queues on the switch.</td>
<td>Yes</td>
</tr>
<tr>
<td>Propagate a service policy by reconfiguring the DSCP in outbound IP packets according to packet type. The packet is placed in an outbound port queue according to the 802.1p priority configured for that DSCP policy. (The policy assumes that downstream devices can be configured to recognize the DSCP in IP packets and implement the service policy it indicates.)</td>
<td></td>
</tr>
<tr>
<td>Use VLAN-tagged ports to include packet priority as an 802.1p value to downstream devices.</td>
<td>Yes</td>
</tr>
</tbody>
</table>

1 In this mode the configuration is fixed. You cannot change the automatic priority assignment when using IP-ToS Precedence as a QoS classifier.

2 Not available on the 3400cl/6400cl switches.

2. If you want 802.1p priority settings to be included in outbound packets, ensure that tagged VLANs are configured on the appropriate downstream links.
3. Determine the actual QoS configuration changes you will need to make on each QoS-capable device in your network in order to implement the desired policy. Also, if you want downstream devices to read and use DSCPs in IP packets from the switch, configure them to do so by enabling ToS Differentiated Service mode and making sure the same DSCP policies are configured.

4. If you are planning a QoS configuration on a 3400cl or 6400cl switch, refer to the next section, “Planning QoS for the Series 3400cl/6400cl Switches”.

**Note**

On the 3400cl/6400cl switches, ACLs and Rate-Limiting use the same internal resources (per-port rules) as QoS. For this reason, plus the limit on per-port rule resources, it is important to consider rule usage when preparing to configure QoS on the switch. For more information, refer to the next section, “Planning QoS for the Series 3400cl/6400cl Switches”.

**Planning QoS for the Series 3400cl/6400cl Switches**

QoS, ACLs, and Rate Limiting share certain internal, per-port resources on 3400cl/6400cl switches. Thus, QoS (and ACL) configurations can load internal resources in ways that require more careful attention to resource usage when planning a configuration using these features. Otherwise, there is an increased possibility of oversubscribing some switch resources, which means that at some point the switch would not support further QoS, ACL, and/or Rate-Limiting configuration. This section describes resource planning for QoS features on a 3400cl or 6400cl switch. For ACL planning, refer to chapter 10, “Access Control Lists (ACLs) for the Series 3400cl and Series 6400cl Switches”. For information on Rate-Limiting, refer to the “Rate-Limiting” section in the chapter titled “Port Traffic Controls” of the *Management and Configuration Guide* for your switch.

**Prioritizing and Monitoring QoS, ACL, and Rate Limiting Feature Usage on the 3400cl/6400cl Switches**

If you want to configure QoS and either ACLs or Rate-Limiting (or both) on a 3400cl or 6400xl switch, plan and implement your configuration in descending order of feature importance. This will help to ensure that the most important features are configured first. Also, if insufficient resources become a problem, this approach can help you recognize how to distribute the desired feature implementations across multiple switches to achieve your objectives. For example, adding ACLs consumes resources faster than QoS rules and policies. If QoS is more important on a particular 3400cl or 6400cl switch than ACLs,
then you should plan and configure your QoS resource usage first for that switch. If insufficient resources remain for all of the ACL implementation you want, try spreading this implementation across multiple switches.

QoS Resource Usage and Monitoring on 3400cl/6400cl Switches

QoS, ACLs, multicast protocols, and Rate-Limiting configurations on the 3400cl/6400cl switches use rule resources on a per-port basis. Per-Port rule usage is reserved as shown below:

**Table 8-9. Rule Maximums on the 3400cl/6400cl Switches**

<table>
<thead>
<tr>
<th>Feature</th>
<th>Maximum Rules Available Per-Port</th>
</tr>
</thead>
<tbody>
<tr>
<td>QoS and Rate-Limiting(^\d)</td>
<td>120 maximum in any feature combination</td>
</tr>
<tr>
<td>ACLs and IGMP(^\d)</td>
<td></td>
</tr>
</tbody>
</table>

\(^\d\)Configuring Rate-Limiting on a port uses one per-port rule on that port.
\(^\d\)Configuring IGMP on any static VLAN uses one per-port ACL mask on all ports.

Table 8-10 describes rule resource use for each QoS classifier type.

**Table 8-10. QoS Rule Resource Usage**

<table>
<thead>
<tr>
<th>QoS Classifier</th>
<th>Port Application</th>
<th>Rules Used</th>
</tr>
</thead>
<tbody>
<tr>
<td>TCP and UDP</td>
<td>All Ports in the Switch</td>
<td>2 per TCP or UDP Application</td>
</tr>
<tr>
<td>Device Priority</td>
<td>&quot; &quot; &quot; &quot; &quot; &quot;</td>
<td>2 per IP Address</td>
</tr>
<tr>
<td>ToS IP-Precedence</td>
<td>&quot; &quot; &quot; &quot; &quot;</td>
<td>8</td>
</tr>
<tr>
<td>ToS Diff-Services</td>
<td>&quot; &quot; &quot; &quot; &quot;</td>
<td>1 per Codepoint(^\d)</td>
</tr>
<tr>
<td>VLAN</td>
<td>All Ports in the VLAN</td>
<td>1 per VLAN</td>
</tr>
<tr>
<td>Source Port</td>
<td>Specified Port(s)</td>
<td>1 per Port(^\d)</td>
</tr>
</tbody>
</table>

\(^\d\)When the ToS Diff-Services mode is enabled, each codepoint (DSCP) policy configured in the DSCP map and each (inbound) codepoint assigned to a DSCP policy use one rule per-port. When this mode is disabled, all rules used by the ToS Diff-Services option, including any DSCP policies configured in the DSCP map, become available for other uses.
\(^\d\)Enabling source-port QoS and rate-limiting on the same port uses one rule.
The following two CLI commands are unique to the 3400cl/6400cl switches and are useful for planning and monitoring rule usage in a QoS configuration.

**Syntax:** `qos resources help`

*Provides a quick reference on how QoS and ACLs use rule resources for each configuration option. Includes most of the information in table 8-10, plus an ACL usage summary.*

**Syntax:** `show qos resources`

*Shows the number of rules currently available on each port. This command is useful for verifying rule availability as you proceed with configuring QoS, ACL, and/or Rate-Limiting features available on the switch.*

Managing QoS Resource Consumption on the 3400cl/6400cl Switches

As shown in table 8-10, QoS classifiers use 1, 2, or 8 rules depending on the classifier selected. Extensive QoS and ACL configurations, with or without applying Rate-Limiting or a multicast protocol, can either fully subscribe the 120 rules available on a given port or leave an insufficient number of rules available for configuring another QoS policy on the switch. If there are not enough rules on the port to support another QoS policy, you cannot configure an additional policy on that port. Because most QoS features are applied to all ports, having one or more ports with insufficient rules remaining to support another QoS policy limits further QoS configurations on the switch to:

- Source-port QoS on ports that have sufficient unused rules
- VLAN QoS on VLANs where all of the member ports have sufficient unused rules

(This can also block any further ACL and—if not already configured—a Rate-Limiting configuration on the affected port.)

Problems with insufficient rules available on a port can occur in either of the following QoS scenarios:

- Attempting to configure a policy when one or more of the affected ports have insufficient rules available
- Attempting to add a port to a QoS-configured VLAN where the policy already on the VLAN requires more rule resources than the port has available.
Configuring a Policy When There Are Not Enough Rules Available On a Target Port. Attempting to configure a QoS policy on the switch, on a VLAN, or on selected ports when there are not enough rules available on one or more ports that are subject to the command results in the following:

- The policy is not configured on any ports subject to the command.
- The CLI displays the following message:

  Unable to add this QoS rule. Maximum number (120) already reached.

Adding a Port to a QoS-Configured VLAN Without Enough Rules Available on the Port. When you add a port to an existing, QoS-configured VLAN, the switch attempts to apply the VLAN’s QoS configuration to the port. If the port has insufficient rule resources to add the VLAN’s QoS configuration:

- The port is added to the VLAN.
- The QoS classifiers configured on the VLAN are not added to the port, which means that the port does not honor the QoS policies configured for the VLAN.
- The switch generates this message in the Event Log:

  cos: Vlan 1 QoS not configured on all new ports.
  Some QoS resources exceeded

Troubleshooting a Shortage of Per-Port Rule Resources on the 3400cl/6400cl Switches

The lack of available rules is caused by existing QoS, ACL, and (if configured) Rate-Limiting configurations consuming the available rules on one or more ports. Do the following to enable configuration of the desired policy:

1. Use the show qos resources command to identify the port(s) on which there are insufficient rule resources. For example, figure 8-3 includes ports that can be the source of problems due to rule consumption by policies configured earlier:
Use Det

</tr>
</tbody>
</table>

At a minimum, the policies configured on port 5 must be reduced to free up enough rule resources to add a new QoS policy. Depending on the QoS policy you want to add, existing policies on ports 3 and 4 may have to be reduced.

Port 3 has enough rules available to accept any policy that uses 1 or 2 rules.

Port 4 can accept only a policy that uses one rule.

Port 5 is fully subscribed and cannot accept any new policies.

Figure 8-3. Example of Inspecting Available Rule Resources

2. Use show commands to identify the currently configured QoS, ACL, and Rate-Limiting policies.

3. Determine which of the existing policies you can remove to free up rule resources for the QoS policy you want to implement. Depending on your network topology and configuration, you can free up rule resources by moving some policies to other devices. Another alternative is to inspect the switch’s existing QoS, ACL, and Rate-Limiting configurations for unnecessary entries or inefficient applications that could be removed or revised to achieve the desired policies with less resource usage. Tables 8-9 and 8-10 on page 8-17, or the information displayed by the qos resources help command, can help you to determine the resource usage of QoS and ACL policies.

Examples of QoS Resource Usage on 3400cl/6400cl Switches

Demonstrating Differing Resource Usage on Different Ports. Suppose that VLANs 111 and 222 on a 3400cl or 6400cl switch are configured for VLAN QoS. Also, device-priority QoS is configured for five IP addresses. The VLAN QoS affects only the ports that belong to VLANs 111 and 222. The device-priority QoS affects all ports on the switch. If ports 1 and 2 belong to both VLANs and ports 3 and 4 belong only to VLAN 222, then these two pairs of ports will differ in how many rules they use. Ports 5 through 24 do not belong to the VLANs, and so will use fewer rules than ports 1 through 4.

<td>No</td>
<td>2 rules per device priority QoS instance</td>
</tr>
</tbody>
</table>

All ports are configured for five QoS device priorities. VLANs 111 and 222 are configured for QoS priority.

Ports 1 and 2 use 12 rules; 10 for implementing the 5 device priority QoS instances and one each for implementing the 2 VLAN QoS instances (111 and 222).

Ports 3 and 4 use 11 rules; 10 for implementing the 5 device priority QoS instances on 1 for implementing the single VLAN QoS instance (VLAN 222).

The remaining ports use only ten rules for implementing the five device priority QoS instances.
Demonstrating How the Switch Uses Resources in DSCP Configurations. In the default configuration, the DSCP map is configured with one DSCP policy (Expedited Forwarding; 101110 with a “7” priority) but, because no ToS Diff-Services options are configured, no rules are used. If ToS Diff-Services mode is enabled, then one rule is immediately used for this codepoint. Adding a new DSCP policy (for example, 001111 with a “5” priority) and then configuring ToS Diff-Services to assign inbound packets with a codepoint of 001010 to the 001111 policy implements all policies configured in the DSCP map and, in this case, uses three rules; one for each codepoint invoked in the switch’s current DSCP configuration (101110—the default, 001111, and 001010). Adding another Diff-Services assignment, such as assigning inbound packets with a codepoint of 000111 to the Expedited Forwarding policy (101110), would use one more rule on all ports.

Figure 8-6. Example of Rule Usage When a Configuration Includes DSCP-Map and Type-of-ServiceOptions

Assigning inbound packets with 001010 in the ToS byte to the newly created 001111 policy enables ToS Diff-Services mode. Because the default DSCP map already includes the Expedited Delivery (101110) policy, enabling ToS Diff-Services uses three rules on each port; one for each configured codepoint (101110, 001010, and 001111). As a result, the available rule count drops by 3 to 117.

**Note**

In addition to the information in this section on the various QoS classifiers, refer to “QoS Operating Notes and Restrictions” on page 8-73.

**Viewing the QoS Configuration**

All of these commands are available on the 5300xl and 4200v1 switches. All except the `protocol-priority` command are available on the 3400cl/6400cl switches. Examples of the `show qos` output are included with the example for each priority type.

**Syntax:** show qos <priority-classifier>

- `tcp-udp-port-priority`
  
  *Displays the current TCP/UDP port priority configuration. Refer to figure 8-11 on page 8-31.*

- `device-priority`
  
  *Displays the current device (IP address) priority configuration. Refer to figure 8-12 on page 8-33.*
Using QoS Classifier

Quality of Service (QoS) Classifier

Using QoS Classifiers To Configure Quality of Service for Outbound Traffic

**type-of-service**

Displays the current type-of-service priority configuration. The display output differs according to the ToS option used:

- **IP Precedence:** Refer to figure 8-16 on page 8-38.
- **Diffserve:** Refer to figure 8-18 on page 8-42.

**protocol-priority**

Available on the 5300xl and 4200vl switches. Displays the current protocol priority configuration.

**vlan-priority**

Displays the current VLAN priority configuration. Refer to figure 8-26 on page 8-54.

**port-priority**

Displays the current source-port priority configuration. Refer to figure 8-31 on page 8-59.

**No Override**

By default, the IP ToS, Protocol, VLAN-ID, and (source) port show outputs automatically list **No-override** for priority options that have not been configured. This means that if you do not configure a priority for a specific option, QoS does not prioritize packets to which that option applies, resulting in the **No override** state. In this case, IP packets received through a VLAN-tagged port receive whatever 802.1p priority they carry in the 802.1Q tag in the packet’s header. VLAN-Tagged packets received through an untagged port are handled in the switch with “normal” priority. For example, figure 8-7 below shows a qos VLAN priority output in a switch where non-default priorities exist for VLANs 22 and 33, while VLAN 1 remains in the default configuration.

<table>
<thead>
<tr>
<th>VLAN ID</th>
<th>Apply rule</th>
<th>DSCP</th>
<th>Priority</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>No-override</td>
<td></td>
<td>No-override</td>
</tr>
<tr>
<td>22</td>
<td>Priority</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>33</td>
<td>DSCP</td>
<td>000010</td>
<td>6</td>
</tr>
</tbody>
</table>

This output shows that VLAN 1 is in the default state, while VLANs 22 and 33 have been configured for 802.1p and DSCP Policy priorities respectively.

Figure 8-7. Example of the Show QoS Output for VLAN Priority

8-24
As mentioned in table 8-6, the 3400cl/6400cl switches do not include the layer 3 protocol classifier. However, you can still apply a QoS priority to non-IP Layer 3 protocol traffic by grouping such traffic into separate VLANs, as desired, and then assigning a priority based on VLAN membership.

QoS UDP/TCP Priority

QoS Classifier Precedence: 1

When you use UDP or TCP and a layer 4 Application port number as a QoS classifier, traffic carrying the specified UDP/TCP port number(s) is marked with the UDP/TCP classifier’s configured priority level, without regard for any other QoS classifiers in the switch.

Note

UDP/TCP QoS applications are supported only for IPv4 packets only. For more information on packet-type restrictions, refer to “Details of Packet Criteria and Restrictions for QoS Support”, on page 8-73.

Options for Assigning Priority. Priority control options for TCP or UDP packets carrying a specified TCP or UDP port number include:

- 802.1p priority
- DSCP policy (Assigning a new DSCP and an associated 802.1p priority; inbound packets must be IPv4.)

For a given TCP or UDP port number, you can use only one of the above options at a time. However, for different port numbers, you can use different options.

TCP/UDP Port Number Ranges. There are three ranges:

- Well-Known Ports: 0 - 1023
- Registered Ports: 1024 - 49151
- Dynamic and/or Private Ports: 49152 - 65535

For more information, including a listing of UDP/TCP port numbers, go to the Internet Assigned Numbers Authority (IANA) web site at:

www.iana.org

Then click on:

Protocol Number Assignment Services

P (Under “Directory of General Assigned Numbers” heading)

Port Numbers
Assigning an 802.1p Priority Based on TCP or UDP Port Number

This option assigns an 802.1p priority to (IPv4) TCP or UDP packets as described below.

**Syntax:** qos < udp-port | tcp-port > < tcp or udp port number > priority < 0 - 7 >

Configures an 802.1p priority for outbound packets having the specified TCP or UDP application port number. This priority determines the packet’s queue in the outbound port to which it is sent. If the packet leaves the switch on a tagged port, it carries the 802.1p priority with it to the next downstream device. (Default: Disabled)

**Note:** On 3400cl/6400cl switches, this feature is not supported for IPv4 packets with IP options. For more information on packet-type restrictions, refer to table 8-15 on page 8-73.

`no qos < udp-port | tcp-port > < tcp-udp port number >`

Deletes the specified UDP or TCP port number as a QoS classifier.

`show qos tcp-udp-port-priority`

Displays a listing of all TCP and UDP QoS classifiers currently in the running-config file.

For example, configure and list 802.1p priority for the following UDP and TCP port prioritization:

<table>
<thead>
<tr>
<th>TCP/UDP Port</th>
<th>802.1p Priority for TCP</th>
<th>802.1p Priority for UDP</th>
</tr>
</thead>
<tbody>
<tr>
<td>TCP Port 23 (Telnet)</td>
<td>7</td>
<td>7</td>
</tr>
<tr>
<td>UDP Port 23 (Telnet)</td>
<td>7</td>
<td>7</td>
</tr>
<tr>
<td>TCP Port 80 (World Wide Web HTTP)</td>
<td>2</td>
<td>2</td>
</tr>
<tr>
<td>UDP Port 80 (World Wide Web HTTP)</td>
<td>1</td>
<td>1</td>
</tr>
</tbody>
</table>
Assigning a DSCP Policy Based on TCP or UDP Port Number

The Series 5300xl and Series 4200vl switches do not support DSCP policies on IPv4 packets with IP options. The 3400cl/6400cl switches do not support TCP/UDP QoS policies on packets with IP options. For more information on packet-type restrictions, refer to “Details of Packet Criteria and Restrictions for QoS Support”, on page 8-73.

This option assigns a previously configured DSCP policy (codepoint and 802.1p priority) to (IPv4) TCP or UDP packets having the specified port number. That is, the switch:

1. Selects an incoming IP packet if the TCP or UDP port number it carries matches the port number specified in the TCP or UDP classifier (as shown in figure 8-8, above).

2. Overwrites (re-marks) the packet’s DSCP with the DSCP configured in the switch for such packets.
3. Assigns the 802.1p priority configured in the switch for the new DSCP. (Refer to “Differentiated Services Codepoint (DSCP) Mapping” on page 8-64.)

4. Forwards the packet through the appropriate outbound port queue.

**3400cl/6400cl Switch Restriction.** On the 3400cl/6400cl switches, “mixing” ToS DSCP policies and 802.1p priorities is not recommended. Refer to the Note on page 8-11.

For more on DSCP, refer to “Terminology” on page 8-6.

**Steps for Creating a DSCP Policy Based on TCP/UDP Port Number Classifiers.** This procedure creates a DSCP policy for IPv4 packets carrying the selected UDP or TCP port-number classifier.

1. Identify the TCP or UDP port-number classifier you want to use for assigning a DSCP policy.

2. Determine the DSCP policy for packets carrying the selected TCP or UDP port number.
   a. Determine the DSCP you want to assign to the selected packets. (This codepoint will be used to overwrite (re-mark) the DSCP carried in packets received from upstream devices.)
   b. Determine the 802.1p priority you want to assign to the DSCP.

3. Configure the DSCP policy by using `qos dscp-map` to configure the priority to the codepoint you selected in step 2a. (For details, refer to the example later in this section, and to “Differentiated Services Codepoint (DSCP) Mapping” on page 8-64.)

**Note**

A codepoint must have an 802.1p priority assignment (0 - 7) before you can configure a policy for prioritizing packets by TCP or UDP port numbers. If a codepoint you want to use shows **No-override** in the **Priority** column of the DSCP map (show `qos dscp-map`), then you must assign a 0 - 7 priority before proceeding.

4. Configure the switch to assign the DSCP policy to packets with the specified TCP or UDP port number.
Quality of Service (QoS): Managing Bandwidth More Effectively
Using QoS Classifiers To Configure Quality of Service for Outbound Traffic

Syntax:  qos dscp-map < codepoint > priority < 0 - 7 >

This command is optional if a priority has already been assigned to the < codepoint >. The command creates a DSCP policy by assigning an 802.1p priority to a specific DSCP. When the switch applies this policy to a packet, the priority determines the packet's queue in the outbound port to which it is sent. If the packet leaves the switch on a tagged port, it carries the 802.1p priority with it to the next downstream device. For IPv4 packets, the DSCP will be replaced by the codepoint specified in this command. (Default: No-override for most codepoints. See table 8-14 on page 8-65.)

Syntax:  qos < udp-port | tcp-port > < tcp or udp port number > dscp < codepoint >

Assigns a DSCP policy to outbound packets having the specified TCP or UDP application port number and overwrites the DSCP in these packets with the assigned < codepoint > value. This policy includes an 802.1p priority and determines the packet's queue in the outbound port to which it is sent. (The < codepoint > must be configured with an 802.1p setting. See step 3 on page 8-28.) If the packet leaves the switch on a tagged port, it carries the 802.1p priority with it to the next downstream device. (Default: No-override)

no qos < udp-port | tcp-port > < tcp-udp port number >

Deletes the specified UDP or TCP port number as a QoS classifier.

show qos tcp-udp-port-priority

Displays a listing of all TCP and UDP QoS classifiers currently in the running-config file.
For example, suppose you wanted to assign these DSCP policies to the packets identified by the indicated UDP and TDP port applications:

<table>
<thead>
<tr>
<th>Port Applications</th>
<th>DSCP Policies</th>
<th>DSCP</th>
<th>Priority</th>
</tr>
</thead>
<tbody>
<tr>
<td>23-UDP</td>
<td>000111</td>
<td>7</td>
<td></td>
</tr>
<tr>
<td>80-TCP</td>
<td>000101</td>
<td>5</td>
<td></td>
</tr>
<tr>
<td>914-TCP</td>
<td>000010</td>
<td>1</td>
<td></td>
</tr>
<tr>
<td>1001-UDP</td>
<td>000010</td>
<td>1</td>
<td></td>
</tr>
</tbody>
</table>

1. Determine whether the DSCP policies already have priority assignments, which could indicate use by existing applications. (Also, a DSCP must have a priority configured before you can assign any QoS classifiers to use it.)

```
ProCurve(config)# show qos dscp-map
DSCP -> 802.1p priority mappings
DSCP policy 802.1p tag Policy name
---------- -------------- ---------------
 000000   No-override
 000001   No-override
 000010   No-override
 000011   No-override
 000100   No-override
 000101   No-override
 000110   No-override
 000111   No-override
 001000   No-override
```

Figure 8-9. Display the Current DSCP-Map Configuration

2. Configure the DSCP policies for the codepoints you want to use.

```
ProCurve(config)# qos dscp-map 000111 priority 7
ProCurve(config)# qos dscp-map 000101 priority 5
ProCurve(config)# qos dscp-map 000010 priority 1
ProCurve(config)# show qos dscp-map
DSCP -> 802.1p priority mappings
DSCP policy 802.1p tag Policy name

**Figure 8-11. The Completed DSCP Policy Configuration for the Specified UDP/TCP Port Applications**

The switch will now apply the DSCP policies in figure 8-11 to IPV4 packets received in the switch with the specified UDP/TCP port applications. This means the switch will:

- Overwrite the original DSCPs in the selected packets with the new DSCPs specified in the above policies.
- Assign the 802.1p priorities in the above policies to the selected packets.

**QoS IP-Device Priority**

**QoS Classifier Precedence: 2**

The IP device option, which applies only to IPv4 packets, enables you to use up to the following IP address limits (source or destination) as QoS classifiers:

- 5300xl Switches: 256 IP addresses
- 4200vl Switches: 256 IP addresses
- 3400cl/6400cl Switches: 60 IP addresses

Where a particular device-IP address classifier has the highest precedence in the switch for traffic addressed to or from that device, then traffic received on the switch with that address is marked with the IP address classifier's configured priority level. Different IP device classifiers can have differing priority levels.
**Note**

The switch does not allow a QoS IP-device priority for the Management VLAN IP address, if configured. If there is no Management VLAN configured, then the switch does not allow configuring a QoS IP-device priority for the Default VLAN IP address.

IP address QoS does not support layer-2 SAP encapsulation. For more information on packet-type restrictions, refer to Table 8-15, “Details of Packet Criteria and Restrictions for QoS Support”, on page 8-73.

**Options for Assigning Priority.** Priority control options for packets carrying a specified IP address include:

- 802.1p priority
- DSCP policy (Assigning a new DSCP and an 802.1p priority; inbound packets must be IPv4.)

(For operation when other QoS classifiers apply to the same traffic, refer to “Classifiers for Prioritizing Outbound Packets” on page 8-10.)

For a given IP address, you can use only one of the above options at a time. However, for different IP addresses, you can use different options.

**Assigning a Priority Based on IP Address**

This option assigns an 802.1p priority to all IPv4 packets having the specified IP address as either a source or destination. (If both match, the priority for the IP destination address has precedence.)

**Syntax:**

\``qos device-priority < ip-address > priority < 0 - 7 >``

*Configures an 802.1p priority for outbound packets having the specified IP address. This priority determines the packet’s queue in the outbound port to which it is sent. If the packet leaves the switch on a tagged port, it carries the 802.1p priority with it to the next downstream device. (Default: Disabled)*

\``no qos device-priority < ip-address >``

*Removes the specified IP device-priority QoS classifier and resets the priority for that VLAN to No-override.*

\``show qos device-priority``

*Displays a listing of all IP device-priority QoS classifiers currently in the running-config file.*
For example, configure and list the 802.1p priority for packets carrying the following IP addresses:

<table>
<thead>
<tr>
<th>IP Address</th>
<th>802.1p Priority</th>
</tr>
</thead>
<tbody>
<tr>
<td>10.28.31.1</td>
<td>7</td>
</tr>
<tr>
<td>10.28.31.130</td>
<td>5</td>
</tr>
<tr>
<td>10.28.31.100</td>
<td>1</td>
</tr>
<tr>
<td>10.28.31.101</td>
<td>1</td>
</tr>
</tbody>
</table>

```
ProCurve(config)# qos device-priority 10.28.31.1 priority 7
ProCurve(config)# qos device-priority 10.28.31.130 priority 5
ProCurve(config)# qos device-priority 10.28.31.100 priority 1
ProCurve(config)# qos device-priority 10.28.31.101 priority 1
```

```
ProCurve(config)# show qos device-priority
Device priorities

+----------+----------+-------+-------+
Device Address | Apply rule | DSCP  | Priority |
+----------+----------+-------+-------+
10.28.31.1     | Priority  | 7     | 7      |
10.28.31.130   | Priority  | 5     | 5      |
10.28.31.100   | Priority  | 1     | 1      |
10.28.31.101   | Priority  | 1     | 1      |
```

**Figure 8-12. Example of Configuring and Listing 802.1p Priority Assignments for Packets Carrying Specific IP Addresses**

Assigning a DSCP Policy Based on IP Address

**Note**

On 5300xl and 4200vl switches, DSCP policies cannot be applied to IPv4 packets having IP options. For more information on packet criteria and restrictions, refer to table 8-15 on page 8-73.

This option assigns a previously configured DSCP policy (codepoint and 802.1p priority) to outbound IP packets having the specified IP address (either source or destination). That is, the switch:

1. Selects an incoming IPv4 packet on the basis of the source or destination IP address it carries.
2. Overwrites the packet’s DSCP with the DSCP configured in the switch for such packets, and assigns the 802.1p priority configured in the switch for the new DSCP. (Refer to “Differentiated Services Codepoint (DSCP) Mapping” on page 8-64.)
3. Forwards the packet through the appropriate outbound port queue.
3400cl/6400cl Switch Restriction. On the 3400cl/6400cl switches, “mixing” ToS DSCP policies and 802.1p priorities is not recommended. Refer to the Note on page 8-11.

For more on DSCP, refer to “Terminology” on page 8-6.

Steps for Creating a Policy Based on IP Address. This procedure creates a DSCP policy for IPv4 packets carrying the selected IP address (source or destination).

1. Identify the IP address to use as a classifier for assigning a DSCP policy.
2. Determine the DSCP policy for packets carrying the selected IP address:
   a. Determine the DSCP you want to assign to the selected packets. (This codepoint will be used to overwrite the DSCP carried in packets received from upstream devices.)
   b. Determine the 802.1p priority you want to assign to the DSCP.
3. Configure the DSCP policy by using dscp-map to configure the priority to the codepoint you selected in step 2a. (For details, refer to “Differentiated Services Codepoint (DSCP) Mapping” on page 8-64.)

Notes

A codepoint must have an 802.1p priority assignment (0 - 7) before you can configure a policy for prioritizing packets by IP address. If a codepoint you want to use shows No-override in the Priority column of the DSCP map (show qos dscp-map), then you must assign a 0 - 7 priority before proceeding.

On 5300xl and 4200vl switches, DSCP policies cannot be applied to IPv4 packets having IP options. For more information on packet criteria and restrictions, refer to 8-15 on page 8-73.

4. Configure the switch to assign the DSCP policy to packets with the specified IP address.

Syntax: qos dscp-map < codepoint > priority < 0 - 7 >

This command is optional if a priority is already assigned to the < codepoint >. The command creates a DSCP policy by assigning an 802.1p priority to a specific DSCP. When the switch applies this policy to a packet, the priority determines the packet’s queue in the outbound port to which it is sent. If the packet leaves the switch on a tagged port, it carries the 802.1p priority with it to the next downstream device. If the packet is IPv4, the packet’s DSCP will be replaced by the codepoint specified in this command. (Default: For most codepoints, No-override. See figure 8-14 on page 8-65.)
Quality of Service (QoS): Managing Bandwidth More Effectively
Using QoS Classifiers To Configure Quality of Service for Outbound Traffic

Syntax: qos device-priority < ip-address > dscp < codepoint>

Assigns a DSCP policy to packets carrying the specified IP address, and overwrites the DSCP in these packets with the assigned < codepoint > value. This policy includes an 802.1p priority and determines the packet’s queue in the outbound port to which it is sent. If the packet leaves the switch on a tagged port, it carries the 802.1p priority with it to the next downstream device. (Default: No-override)

no qos device-priority < ip-address >

Deletes the specified IP address as a QoS classifier.

show qos device-priority

Displays a listing of all QoS Device Priority classifiers currently in the running-config file.

For example, suppose you wanted to assign these DSCP policies to the packets identified by the indicated IP addresses:

<table>
<thead>
<tr>
<th>IP Address</th>
<th>DSCP Policies</th>
<th>DSCP</th>
<th>Priority</th>
</tr>
</thead>
<tbody>
<tr>
<td>10.28.31.1</td>
<td>000111</td>
<td>00011</td>
<td>7</td>
</tr>
<tr>
<td>10.28.31.130</td>
<td>000101</td>
<td>00010</td>
<td>5</td>
</tr>
<tr>
<td>10.28.31.100</td>
<td>000010</td>
<td>00000</td>
<td>1</td>
</tr>
<tr>
<td>10.28.31.101</td>
<td>000010</td>
<td>00000</td>
<td>1</td>
</tr>
</tbody>
</table>

1. Determine whether the DSCPs already have priority assignments, which could indicate use by existing applications. This is not a problem if the configured priorities are acceptable for all applications using the same DSCP. (Refer to the “Note On Changing a Priority Setting” on page 8-67. Also, a DSCP must have a priority configured before you can assign any QoS classifiers to use it.)

```
ProCurve(config)# show qos dscp-map
DSCP -> 802.1p priority mappings
DSCP policy 802.1p tag  Policy name
---------------------------------------------------------------
0000000  No-override
0000001  No-override
0000100  No-override
0000111  No-override
0001000  No-override
0001010  No-override
0001100  No-override
0001110  No-override
0001111  No-override

Figure 8-13. Display the Current DSCP-Map Configuration
```
2. Configure the priorities for the DSCPs you want to use.

```
ProCurve(config)# qos dscp-map 000111 priority 7
ProCurve(config)# qos dscp-map 000101 priority 5
ProCurve(config)# qos dscp-map 000010 priority 1
ProCurve(config)# show qos dscp-map
DSCP -> 802.1p priority mappings
DSCP policy 802.1p tag Policy name
----------------- ---------------------
000000 No-override
000001 No-override
000010 1
000011 No-override
000100 No-override
000101 5
000110 No-override
000111 7
001000 No-override

Figure 8-14. Assigning 802.1p Priorities to the Selected DSCPs
```

3. Assign the DSCP policies to the selected device IP addresses and display the result.

```
ProCurve(config)# qos device-priority 10.28.31.1 dscp 000111
ProCurve(config)# qos device-priority 10.28.31.130 dscp 000101
ProCurve(config)# qos device-priority 10.28.31.100 dscp 000010
ProCurve(config)# qos device-priority 10.28.31.101 dscp 000010
ProCurve(config)# show qos device-priority
Device priorities
Device Address Apply rule | DSCP   | Priority
----------------- ---------------+--------+-------
10.28.31.1  DSCP       | 000111 | 7
10.28.31.130 DSCP      | 000101 | 5
10.28.31.100 DSCP      | 000010 | 1
10.28.31.101 DSCP      | 000010 | 1

Figure 8-15. The Completed Device-Priority/Codepoint Configuration
```

The switch will now apply the DSCP policies in figure 8-14 to IPv4 packets received on the switch with the specified IP addresses (source or destination). This means the switch will:

- Overwrite the original DSCPs in the selected packets with the new DSCPs specified in the above policies.
- Assign the 802.1p priorities in the above policies to the appropriate packets.

---

8-36
QoS IP Type-of-Service (ToS) Policy and Priority

**QoS Classifier Precedence: 3**

This feature applies only to IPv4 traffic and performs either of the following:

- **ToS IP-Precedence Mode:** All IP packets generated by upstream devices and applications include precedence bits in the ToS byte. Using this mode, the switch uses these bits to compute and assign the corresponding 802.1p priority.

- **ToS Differentiated Services (Diffserv) Mode:** This mode requires knowledge of the codepoints set in IP packets by the upstream devices and applications. It uses the ToS codepoint in IP packets coming from upstream devices and applications to assign 802.1p priorities to the packets. You can use this option to do both of the following:
  
  - **Assign a New Prioritization Policy:** A “policy” includes both a codepoint and a corresponding 802.1p priority. This option selects an incoming IPv4 packet on the basis of its codepoint and assigns a new codepoint and corresponding 802.1p priority. (Use the `qos dscp-map` command to specify a priority for any codepoint—page 8-64.)
  
  - **Assign an 802.1p Priority:** This option reads the DSCP of an incoming IPv4 packet and, without changing this codepoint, assigns the 802.1p priority to the packet, as configured in the DSCP Policy Table (page 8-64). This means that a priority value of 0 - 7 must be configured for a DSCP before the switch will attempt to perform a QoS match on the packet’s DSCP bits.

Before configuring the ToS Diffserv mode, you must use the `dscp-map` command to configure the desired 802.1p priorities for the codepoints you want to use for either option. This command is illustrated in the following examples and is described under “Differentiated Services Codepoint (DSCP) Mapping” on page 8-64.

Unless IP-Precedence mode and Diffserv mode are both disabled (the default setting), enabling one automatically disables the other. For more on ToS operation, refer to “Details of QoS IP Type-of-Service” on page 8-47.

**3400cl/6400cl Switch Restriction.** On the 3400cl/6400cl switches, “mixing” ToS DSCP policies and 802.1p priorities is not recommended. Refer to the Note on page 8-11.
Assigning an 802.1p Priority to IPv4 Packets on the Basis of the ToS Precedence Bits

If a device or application upstream of the switch sets the precedence bits in the ToS byte of IPv4 packets, you can use this feature to apply that setting for prioritizing packets for outbound port queues. If the outbound packets are in a tagged VLAN, this priority is carried as an 802.1p value to the adjacent downstream devices.

**Syntax:** qos type-of-service ip-precedence

*Causes the switch to automatically assign an 802.1p priority to all IPv4 packets by computing each packet's 802.1p priority from the precedence bits the packet carries. This priority determines the packet's queue in the outbound port to which it is sent. If the packet leaves the switch on a tagged port, it carries the 802.1p priority with it to the next downstream device.* (ToS IP Precedence Default: Disabled)

no qos type-of-service

*Disables all ToS classifier operation, including prioritization using the precedence bits.*

show qos type-of-service

*When ip-precedence is enabled (or if neither ToS option is configured), shows the ToS configuration status. If diff-services is enabled, lists codepoint data as described under “Assigning a DSCP Policy on the Basis of the DSCP in IPv4 Packets Received from Upstream Devices” on page 8-43.*

With this option, prioritization of outbound packets relies on the IP-Precedence bit setting that IP packets carry with them from upstream devices and applications. To configure and verify this option:

```
ProCurve(config)# qos type-of-service ip-precedence
ProCurve(config)# show qos type-of-service
   Type of Service [Disabled] : IP Precedence
```

![Figure 8-16. Example of Enabling ToS IP-Precedence Prioritization](image)

To replace this option with the ToS diff-services option, just configure **diff-services** as described below, which automatically disables IP-Precedence. To disable IP-Precedence without enabling the diff-services option, use this command:
Assigning an 802.1p Priority to IPv4 Packets on the Basis of Incoming DSCP

One of the best uses for this option is on an interior switch where you want to honor (continue) a policy set on an edge switch. That is, it enables you to select incoming packets having a specific DSCP and forward these packets with the desired 802.1p priority. For example, if an edge switch “A” marks all packets received on port A5 with a particular DSCP, you can configure a downstream (interior) switch “B” to handle such packets with the desired priority (regardless of whether 802.1Q tagged VLANs are in use).

To do so, assign the desired 802.1p priority to the same codepoint that the upstream or edge switch assigns to the selected packets. When the downstream switch receives an IPv4 packet carrying one of these codepoints, it assigns the configured priority to the packet and sends it out the appropriate priority queue. (The packet retains the codepoint it received from the upstream or edge switch). You can use this option concurrently with the diffserv DSCP Policy option (described later in this section), as long as the DSCPs specified in the two options do not match.

Operating Notes

Different applications may use the same DSCP in their IP packets. Also, the same application may use multiple DSCPs if the application originates on different clients, servers, or other devices. Using an edge switch enables you to select the packets you want and mark them with predictable DSCPs that can be used by downstream switches to honor policies set in the edge switch.
When enabled, the switch applies direct 802.1p prioritization to all packets having codepoints that meet these criteria:

- The codepoint is configured with an 802.1p priority in the DSCP table. (Codepoints configured with **No-override** are not used.)
- The codepoint is not configured for a new DSCP policy assignment.

Thus, the switch does not allow the same incoming codepoint (DSCP) to be used simultaneously for directly assigning an 802.1p priority and also assigning a DSCP policy. For a given incoming codepoint, if you configure one option and then the other, the second overwrites the first.

To use this option:

1. Identify a DSCP used to set a policy in packets received from an upstream or edge switch.

2. Determine the 802.1p priority (0 - 7) you want to apply to packets carrying the identified DSCP. (You can either maintain the priority assigned in the upstream or edge switch, or assign a new priority.)

3. Use `qos dscp-map < codepoint > priority < 0 - 7 >` to assign the 802.1p priority you want to the specified DSCP. (For more on this topic, refer to “Differentiated Services Codepoint (DSCP) Mapping” on page 8-64.)

4. Enable **diff-services**

```
Syntax: qos type-of-service diff-services < codepoint >

Causes the switch to read the < codepoint > (DSCP) of an incoming IPv4 packet and, when a match occurs, assign a corresponding 802.1p priority, as configured in the switch’s DSCP table (page 8-65).
```

```
no qos type-of-service

Disables all ToS classifier operation.
```
no qos dscp-map < codepoint >

Disables direct 802.1p priority assignment to packets carrying the < codepoint > by reconfiguring the codepoint priority assignment in the DSCP table to No-override. Note that if this codepoint is in use as a DSCP policy for another diffserv codepoint, you must disable or redirect the other diffserv codepoint’s DSCP policy before you can disable or change the codepoint. For example, in figure 8-18 you cannot change the priority for the 000000 codepoint until you redirect the DSCP policy for 000001 away from using 000000 as a policy. (Refer to “Note On Changing a Priority Setting” on page 8-67. Refer also to “Differentiated Services Codepoint (DSCP) Mapping” on page 8-64.)

show qos type-of-service

Displays current Type-of-Service configuration. In diffserv mode it also shows the current direct 802.1p assignments and the current DSCP assignments covered later in this section.

For example, an edge switch “A” in an untagged VLAN assigns a DSCP of 000110 on IP packets it receives on port A6, and handles the packets with high priority (7). When these packets reach interior switch “B” you want the switch to handle them with the same high priority. To enable this operation you would
configure an 802.1p priority of 7 for packets received with a DSCP of 000110, and then enable **diff-services**:

```plaintext
ProCurve(config)# show qos type-of-service
Type of Service [Disabled] : Disabled

<table>

<td>.</td>
<td>.</td>
</tr>
<tr>
<td>.</td>
<td>.</td>
<td>.</td>
</tr>
</tbody>
</table>

Executing this command displays the current ToS configuration and shows that the selected DSCP is not currently in use.

The **000110** codepoint is unused, and thus available for directly assigning an 802.1p priority without changing the packet's DSCP.

**Note:** All codepoints without a "DSCP Policy" entry are available for direct 802.1p priority assignment.

**Figure 8-18. Example Showing Codepoints Available for Direct 802.1p Priority Assignments**

```plaintext
ProCurve(config)# qos dscp-map 000110 priority 7
ProCurve(config)# qos type-of-service diff-services

ProCurve(config)# show qos type-of-service
Type of Service [Disabled] : Differentiated Services

</tbody>
</table>

Outbound IP packets with a DSCP of **000110** will have a priority of **7**.

Notice that codepoints **000000** and **001001** are named as DSCP policies by other codepoints (**000001** and **000110** respectively). This means they are not available for changing to a different 802.1p priority.

**Figure 8-19. Example of a Type-of-Service Configuration Enabling Both Direct 802.1p Priority Assignment and DSCP Policy Assignment**
Assigning a DSCP Policy on the Basis of the DSCP in IPv4 Packets Received from Upstream Devices

The preceding section describes how to forward a policy set by an edge (or upstream) switch. This option changes a DSCP policy in an IPv4 packet by changing its IP ToS codepoint and applying the priority associated with the new codepoint. (A DSCP policy consists of a differentiated services codepoint and an associated 802.1p priority.) You can use this option concurrently with the diffserv 802.1p priority option (above), as long as the DSCPs specified in the two options do not match.

To use this option to configure a change in policy:

1. Identify a DSCP used to set a policy in packets received from an upstream or edge switch.
2. Create a new policy by using `qos dscp-map < codepoint> priority < 0 - 7 >` to configure an 802.1p priority for the codepoint you will use to overwrite the DSCP the packet carries from upstream. (For more on this topic, refer to “Differentiated Services Codepoint (DSCP) Mapping” on page 8-64.)
3. Use `qos type-of-service diff-services < incoming-DSCP > dscp < outgoing-DSCP>` to change the policy on packets coming from the edge or upstream switch with the specified incoming DSCP.

(Figure 8-17 on page 8-39 illustrates this scenario.)

**Note**

On 5300xl and 4200vl switches, DSCP policies (codepoint re-marking) cannot be applied to outbound IPv4 packets having IP options. (The 802.1p priority in the VLAN tag is applied.) For more information on packet criteria and restrictions, refer to 8-15 on page 8-73.

**3400cl/6400cl Switch Restriction.** On the 3400cl/6400cl switches, “mixing” ToS DSCP policies and 802.1p priorities is not recommended. Refer to the Note on page 8-11.

**Syntax:** `qos type-of-service diff-services

   Enables ToS diff-services.`
Quality of Service (QoS): Managing Bandwidth More Effectively
Using QoS Classifiers To Configure Quality of Service for Outbound Traffic

**Syntax:** qos type-of-service diff-services < current-codepoint > dscp < new-codepoint >

Configures the switch to select an incoming IP packet carrying the <current-codepoint> and then use the <new-codepoint> to assign a new, previously configured DSCP policy to the packet. The policy overwrites the <current-codepoint> with the <new-codepoint> and assigns the 802.1p priority specified by the policy. (Use the qos dscp-map command to define the priority for the DSCPs—page 8-64.)

**Syntax:** no qos type-of-service

Disables all ToS classifier operation. Current ToS DSCP policies and priorities remain in the configuration and will become available if you re-enable ToS diff-services.

**Syntax:** no qos type-of-service [diff-services < codepoint >]

Deletes the DSCP policy assigned to the <codepoint> and returns the <codepoint> to the 802.1p priority setting it had before the DSCP policy was assigned. (This will be either a value from 0 - 7 or No-override.)

**Syntax:** show qos type-of-service

Displays a listing of codepoints, with any corresponding DSCP policy re-assignments for outbound packets. Also lists the (802.1p) priority for each codepoint that does not have a DSCP policy assigned to it.

For example, suppose you want to configure the following two DSCP policies for packets received with the indicated DSCPs.

<table>
<thead>
<tr>
<th>Received DSCP</th>
<th>Policy DSCP</th>
<th>802.1p Priority</th>
<th>Policy Name (Optional)</th>
</tr>
</thead>
<tbody>
<tr>
<td>001100</td>
<td>000010</td>
<td>6</td>
<td>Level 6</td>
</tr>
<tr>
<td>001101</td>
<td>000101</td>
<td>4</td>
<td>Level 4</td>
</tr>
</tbody>
</table>

1. Determine whether the DSCPs already have priority assignments, which could indicate use by existing applications. This is not a problem as long as the configured priorities are acceptable for all applications using the same DSCP. (Refer to the “Note On Changing a Priority Setting” on page 8-67. Also, a DSCP must have a priority configured before you can assign any QoS classifiers to use it.)
Quality of Service (QoS): Managing Bandwidth More Effectively
Using QoS Classifiers To Configure Quality of Service for Outbound Traffic

```
ProCurve(config)# show qos dscp-map
DSCP -> 802.p priority mappings
DSCP policy 802.1p tag   Policy name
------------------------ ---------------
000000     No-override
000001     No-override
000010     No-override
000011     No-override
000100     No-override
000101     No-override
000110     No-override
000111     No-override
                   ...
                   ...

Figure 8-20. Display the Current DSCP-Map Configuration

The DSCPs for this example have not yet been assigned an 802.1p priority level.

2. Configure the policies in the DSCP table:

```
ProCurve(config)# qos dscp-map 000010 priority 6 name 'Level 6'
ProCurve(config)# qos dscp-map 000101 priority 4 name 'Level 4'

ProCurve(config)# show qos dscp-map
DSCP -> 802.p priority mappings
DSCP policy 802.1p tag   Policy name
------------------------ ---------------
000000     No-override
000001     No-override
000010     6           Level 6
000011     No-override
000100     No-override
000101     4           Level 4
000110     No-override
000111     No-override
                   ...
                   ...
```

Figure 8-21. Example of Policies Configured (with Optional Names) in the DSCP Table
3. Assign the policies to the codepoints in the selected packet types.

```text
ProCurve(config)# qos type-of-service diff-services 001100 dscp 000010
ProCurve(config)# qos type-of-service diff-services 001101 dscp 000101
```

Figure 8-22. Example of Policy Assignment to Outbound Packets on the Basis of the DSCP in the Packets Received from Upstream Devices

The specified DSCP policies overwrite the original DSCPs on the selected packets, and use the 802.1p priorities previously configured in the DSCP policies in step 2.
Details of QoS IP Type-of-Service

IP packets include a Type of Service (ToS) byte. The ToS byte includes:

- **A Differentiated Services Codepoint (DSCP):** This element is comprised of the upper six bits of the ToS byte. There are 64 possible codepoints.
  - In the 5300xl and 4200vl switches, the default `qos` configuration includes some codepoints with 802.1p priority settings for Assured-Forwarding and Expedited Forwarding (codepoint 101110), while others are unused (and listed with `No-override` for a Priority).
  - In the 3400cl/6400cl switches, the default `qos` configuration includes the codepoint (7) having the 802.1p priority setting for Expedited Forwarding, while all others, including the Assured-Forwarding codepoints, are unused (and listed with `No-override` for a Priority).

Refer to figure 8-14 on page 8-65 for an illustration of the default DSCP policy table.

Using the `qos dscp map` command, you can configure the switch to assign different prioritization policies to IPv4 packets having different codepoints. As an alternative, you can configure the switch to assign a new codepoint to an IPv4 packet, along with a corresponding 802.1p priority (0-7). To use this option in the simplest case, you would:

a. Configure a specific DSCP with a specific priority in an edge switch.

b. Configure the switch to mark a specific type of inbound traffic with that DSCP (and thus create a policy for that traffic type).

c. Configure the internal switches in your LAN to honor the policy.

(For example, you could configure an edge switch to assign a codepoint of 000001 to all packets received from a specific VLAN, and then handle all traffic with that codepoint at high priority.)

For a codepoint listing and the commands for displaying and changing the DSCP Policy table, refer to “Differentiated Services Codepoint (DSCP) Mapping” on page 8-64.

**Restriction:** On the 3400cl/6400cl switches, “mixing” ToS DSCP policies and 802.1p priorities is not recommended. Refer to the Note on page 8-11.

- **Precedence Bits:** This element is a subset of the DSCP and is comprised of the upper three bits of the ToS byte. When configured to do so, the switch uses the precedence bits to determine a priority for handling the associated packet. (The switch does not change the setting of the precedence bits.) Using the ToS Precedence bits to prioritize IPv4 packets relies on priorities set in upstream devices and applications.
Quality of Service (QoS): Managing Bandwidth More Effectively
Using QoS Classifiers To Configure Quality of Service for Outbound Traffic

Figure 8-23 shows an example of the ToS byte in the header for an IPv4 packet, and illustrates the diffserv bits and precedence bits in the ToS byte. (Note that the Precedence bits are a subset of the Differentiated Services bits.)

<table>

</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>IP Precedence (Value = 0 - 7)</td>
</tr>
</tbody>
</table>

**IP Packet Sent Out an Untagged Port in a VLAN**

- Depending on the value of the IP Precedence bits in the packet's ToS field, the packet will go to one of four outbound port queues in the switch:
  - 1 - 2 = low priority
  - 0 - 3 = normal priority
  - 4 - 5 = high priority
  - 6 - 7 = high priority
- For a given packet carrying a ToS codepoint that the switch has been configured to detect:
  - Change the codepoint according to the configured policy and assign the 802.1p priority specified for the new codepoint in the DSCP Policy Table (page 8-64).
  - Do not change the codepoint, but assign the 802.1p priority specified for the existing codepoint in the DSCP Policy Table (page 8-64).
- Depending on the 802.1p priority used, the packet will leave the switch through one of the following queues:
  - 1 - 2 = low priority
  - 0 - 3 = normal priority
  - 4 - 5 = high priority
  - 6 - 7 = high priority
- If No-override (the default) has been configured for a specified codepoint, then the packet is not prioritized by ToS and, by default, is sent to the “normal priority” queue.

Quality of Service (QoS): Managing Bandwidth More Effectively
Using QoS Classifiers To Configure Quality of Service for Outbound Traffic

QoS Layer-3 Protocol Priority (5300xl and 4200vl Switches Only)

(This feature is available only on the Series 5300xl and 4200vl switches.)

QoS Classifier Precedence: 4

The QoS protocol option enables you to use these protocols as QoS classifiers:

- IP
- ARP
- Appletalk
- Netbeui
- IPX
- DEC_LAT
- SNA

Options for Assigning Priority. Priority control for the Layer-3 protocol classifier includes assigning only the 802.1p priority. The switch does not use this classifier for assigning DSCP-based priority.

Assigning a Priority Based on Layer-3 Protocol

When QoS on the switch is configured with a Layer-3 protocol as the highest-precedence classifier and the switch receives traffic carrying that protocol, then this traffic is assigned the priority configured for this classifier. (For operation when other QoS classifiers apply to the same traffic, refer to “Classifiers for Prioritizing Outbound Packets” on page 8-10.)

Syntax: qos protocol

< ip | ipx | arp | dec_lat | appletalk | sna | netbeui > priority < 0 - 7 >

Configures an 802.1p priority for outbound packets having the specified protocol. This priority determines the packet’s queue in the outbound port to which it is sent. If the packet leaves the switch on a tagged port, it carries the 802.1p priority with it to the next downstream device. You can configure one QoS classifier for each protocol type. (Default: No-override)

no qos protocol

< ip | ipx | arp | dec_lat | appletalk | sna | netbeui >

Disables use of the specified protocol as a QoS classifier and resets the protocol priority to No-override.

show qos protocol

Lists the QoS protocol classifiers with their priority settings.
Quality of Service (QoS): Managing Bandwidth More Effectively
Using QoS Classifiers To Configure Quality of Service for Outbound Traffic

For example:

1. Configure QoS protocol classifiers with IP at 0 (normal), ARP at 5 (medium), and AppleTalk at 7 (high) and display the QoS protocol configuration.

2. Disable the QoS IP protocol classifier, downgrade the ARP priority to 4, and again display the QoS protocol configuration.

Figure 8-24 shows the command sequence and displays for the above steps.

```
ProCurve(config)# qos protocol ip priority 0
ProCurve(config)# qos protocol appletalk priority 7
ProCurve(config)# qos protocol arp priority 5

ProCurve(config)# show qos protocol

Protocol priorities

<table>
<thead>
<tr>
<th>Protocol</th>
<th>Priority</th>
</tr>
</thead>
<tbody>
<tr>
<td>IP</td>
<td>0</td>
</tr>
<tr>

<td>No-override</td>
</tr>
<tr>
<td>AppleTalk</td>
<td>7</td>
</tr>
<tr>
<td>SNA</td>
<td>No-override</td>
</tr>
<tr>
<td>NetBEUI</td>
<td>No-override</td>
</tr>
</tbody>
</table>

ProCurve(config)# no qos protocol ip
ProCurve(config)# qos protocol arp priority 4

ProCurve(config)# show qos protocol

Protocol priorities

<table>
<thead>
<tr>
<th>Protocol</th>
<th>Priority</th>
</tr>
</thead>
<tbody>
<tr>
<td>IP</td>
<td>No-override</td>
</tr>
<tr>
<td>IPX</td>
<td>No-override</td>
</tr>
<tr>
<td>ARP</td>
<td>4</td>
</tr>
<tr>
<td>DEC_LAN</td>
<td>No-override</td>
</tr>
<tr>
<td>AppleTalk</td>
<td>7</td>
</tr>
<tr>
<td>SNA</td>
<td>No-override</td>
</tr>
<tr>
<td>NetBEUI</td>
<td>No-override</td>
</tr>
</tbody>
</table>
```

Figure 8-24. Adding, Displaying, Removing, and Changing QoS Protocol Classifiers
QoS VLAN-ID (VID) Priority

QoS Classifier Precedence: 5

The QoS protocol option enables you to use the VLAN-ID quantities listed below as QoS classifiers.
- 5300xl Switches: Up to 256 VIDs
- 4200vl Switches: Up to 256 VIDs
- 3400cl/6400cl Switches: Up to 120 VIDs

Where a particular VLAN-ID classifier has the highest precedence in the switch for traffic in that VLAN, then traffic received in that VLAN is marked with the VID classifier's configured priority level. Different VLAN-ID classifiers can have differing priority levels.

Options for Assigning Priority. Priority control options for packets carrying a specified VLAN-ID include:
- 802.1p priority
- DSCP policy (Assigning a new DSCP and an associated 802.1p priority; inbound packets must be IPv4.)

(For operation when other QoS classifiers apply to the same traffic, refer to “Classifiers for Prioritizing Outbound Packets” on page 8-10.)

Note

QoS with VID priority applies to static VLANs only, and applying QoS to dynamic VLANs created by GVRP operation is not supported. A VLAN must exist while a subject of a QoS configuration, and eliminating a VLAN from the switch causes the switch to clear any QoS features configured for that VID.

Assigning a Priority Based on VLAN-ID

This option assigns a priority to all outbound packets having the specified VLAN-ID (VID). You can configure this option by either specifying the VLAN-ID ahead of the qos command or moving to the VLAN context for the VLAN you want to configure for priority.
**Quality of Service (QoS): Managing Bandwidth More Effectively**

Using QoS Classifiers To Configure Quality of Service for Outbound Traffic

**Syntax:**  
`vlan <vid> qos priority <0 - 7>`

Configures an 802.1p priority for outbound packets belonging to the specified VLAN. This priority determines the packet’s queue in the outbound port to which it is sent. If the packet leaves the switch on a tagged port, it carries the 802.1p priority with it to the next downstream device. You can configure one QoS classifier for each VLAN-ID. (Default: No-override)

**Syntax:**  
`no vlan <vid> qos`

Removes the specified VLAN-ID as a QoS classifier and resets the priority for that VLAN to No-override.

**Syntax:**  
`show qos vlan-priority`

Displays a listing of the QoS VLAN-ID classifiers currently in the running-config file, with their priority data.

1. For example, suppose that you have the following VLANs configured on the switch and want to prioritize them as shown:

```
ProCurve(config)# show vlan
Status and Counters - VLAN Information
Maximum VLANs to support : 8
Primary VLAN : DEFAULT_VLAN

Set Priority To 2  802.1Q VLAN ID Name        Status
Set Priority To 5
Set Priority To 7
```

![Figure 8-25. Example of a List of VLANs Available for QoS Prioritization](image)

8-53
2. You would then execute the following commands to prioritize the VLANs by VID:

```plaintext
ProCurve(config)# vlan 1 qos priority 2
ProCurve(config)# vlan 20 qos priority 5
ProCurve(config)# vlan 30 qos priority 5
ProCurve(config)# vlan 40 qos priority 7

ProCurve(config)# show qos vlan
VLAN priorities
----------------------------- +---------+---------
VLAN ID  Apply rule | DSCP  | Priority
------------ | ------|---------
     1    | Priority | 2      
     20   | Priority | 5      
     30    | Priority | 5      
     40    | Priority | 7      
```

**Figure 8-26. Configuring and Displaying QoS Priorities on VLANs**

If you then decided to remove VLAN_20 from QoS prioritization:

```plaintext
ProCurve(config)# no vlan 20 qos
ProCurve(config)# show qos vlan
VLAN priorities
----------------------------- +---------+---------
VLAN ID  Apply rule | DSCP  | Priority
------------ | ------|---------
     1    | Priority | 2      
     20   | No-override | No-override |
     30    | Priority | 5      
     40    | Priority | 7      
```

**Figure 8-27. Returning a QoS-Prioritized VLAN to “No-override” Status**

**Assigning a DSCP Policy Based on VLAN-ID (VID)**

This option assigns a previously configured DSCP policy (codepoint and 802.1p priority) to outbound IP packets having the specified VLAN-ID (VID). That is, the switch:

1. Selects an incoming IP packet on the basis of the VLAN-ID it carries.
2. Overwrites the packet’s DSCP with the DSCP configured in the switch for such packets.
3. Assigns the 802.1p priority configured in the switch for the new DSCP. (Refer to “Differentiated Services Codepoint (DSCP) Mapping” on page 8-64.)
4. Forwards the packet through the appropriate outbound port queue.
3400cl/6400cl Switch Restriction. On the 3400cl and 6400cl switches, “mixing” ToS DSCP policies and 802.1p priorities is not recommended. Refer to the Note on page 8-11.

For more on DSCP, refer to “Terminology” on page 8-6.

Steps for Creating a Policy Based on VLAN-ID Classifier.

1. Determine the VLAN-ID classifier to which you want to assign a DSCP policy.
2. Determine the DSCP policy for packets carrying the selected VLAN-ID:
   a. Determine the DSCP you want to assign to the selected packets. (This codepoint will be used to overwrite the DSCP carried in packets received from upstream devices.)
   b. Determine the 802.1p priority you want to assign to the DSCP.
3. Configure the DSCP policy by using `qos dscp-map` to configure the priority for each codepoint. (For details, see the example later in this section, and to “Differentiated Services Codepoint (DSCP) Mapping” on page 8-64.)

   **Note**

   A codepoint must have an 802.1p priority (0 - 7) before you can configure the codepoint for use in prioritizing packets by VLAN-ID. If a codepoint you want to use shows **No-override** in the **Priority** column of the DSCP Policy table, then assign a priority before proceeding.

4. Configure the switch to assign the DSCP policy to packets with the specified VLAN-ID.

   **Syntax:** `qos dscp-map < codepoint > priority < 0 - 7 >`

   This command is optional if a priority has already been assigned to the `<codepoint>`. The command creates a DSCP policy by assigning an 802.1p priority to a specific DSCP. When the switch applies this priority to a packet, the priority determines the packet’s queue in the outbound port to which it is sent. If the packet leaves the switch on a tagged port, it carries the 802.1p priority with it to the next downstream device. If the packet is IPv4, the packet’s DSCP will be replaced by the codepoint specified in this command. (Default: For most codepoints, **No-override**. See figure 8-14 on page 8-65 on page 8-65.)
**Quality of Service (QoS): Managing Bandwidth More Effectively**

**Using QoS Classifiers To Configure Quality of Service for Outbound Traffic**

**Syntax:** `vlan < vid > qos dscp < codepoint>`

Assigns a DSCP policy to packets carrying the specified VLAN-ID, and overwrites the DSCP in these packets with the assigned `< codepoint >` value. This policy includes an 802.1p priority and determines the packet’s queue in the outbound port to which it is sent. If the packet leaves the switch on a tagged port, it carries the 802.1p priority with it to the next downstream device. (Default: No-override)

**Syntax:** `no vlan < vid > qos`

Removes QoS classifier for the specified VLAN.

**Syntax:** `show qos device-priority`

Displays a listing of all QoS VLAN-ID classifiers currently in the running-config file.

For example, suppose you wanted to assign this set of priorities:

<table>
<thead>
<tr>
<th>VLAN-ID</th>
<th>DSCP</th>
<th>Priority</th>
</tr>
</thead>
<tbody>
<tr>
<td>40</td>
<td>000111</td>
<td>7</td>

</tbody>
</table>

1. Determine whether the DSCP values already have priority assignments, which could indicate use by existing applications. This is not a problem as long as the configured priorities are acceptable for all applications using the same DSCP. (Refer to the “Note On Changing a Priority Setting” on page 8-67. Also, a DSCP must have a priority configured before you can assign any QoS classifiers to use it.)

```
ProCurve(config)# show qos dscp-map
DSCP -> 802.p priority mappings
DSCP policy 802.1p tag Policy name
---------- ---------- ------------
000000 No-override
000001 No-override
000010 **No-override**
000011 No-override
000100 No-override
000101 No-override
000110 No-override
000111 No-override
...
```

Figure 8-28. Display the Current Configuration in the DSCP Policy Table
2. Configure the priorities for the DSCPs you want to use.

```
ProCurve(config)# qos dscp-map 000111 priority 7
ProCurve(config)# qos dscp-map 000101 priority 5
ProCurve(config)# qos dscp-map 000010 priority 1
ProCurve(config)# show qos dscp-map

DSCP  ->  802.1p priority mappings
DSCP policy 802.1p tag Policy name
-------------- -------- --------------
000000  No-override
000001  No-override
000010  1
000011  No-override
000100  No-override
000101  5
000110  No-override
000111  7
001000  No-override
...
```

Figure 8-29. Assign Priorities to the Selected DSCPs

3. Assign the DSCP policies to the selected VIDs and display the result.

```
ProCurve(config)# vlan 1 qos dscp 000010
ProCurve(config)# vlan 20 qos dscp 000010
ProCurve(config)# vlan 30 qos dscp 000101
ProCurve(config)# vlan 40 qos dscp 000111

ProCurve(config)# show qos vlan-priority

VLAN priorities

</table>
```

Figure 8-30. The Completed VID-DSCP Priority Configuration

The switch will now apply the DSCP policies in figure 8-30 to packets received on the switch with the specified VLAN-IDs. This means the switch will:

- Overwrite the original DSCPs in the selected packets with the new DSCPs specified in the above policies.
- Assign the 802.1p priorities in the above policies to the appropriate packets.
Quality of Service (QoS): Managing Bandwidth More Effectively
Using QoS Classifiers To Configure Quality of Service for Outbound Traffic

QoS Source-Port Priority

QoS Classifier Precedence: 6
The QoS source-port option enables you to use a packet's source-port on the switch as a QoS classifier. Where a particular source-port classifier has the highest precedence in the switch for traffic entering through that port, then traffic received from the port is marked with the source-port classifier's configured priority level. Different source-port classifiers can have different priority levels.

Options for Assigning Priority on the Switch. Priority control options for packets from a specified source-port include:

- 802.1p priority
- DSCP policy (Assigning a new DSCP and an associated 802.1p priority; inbound packets must be IPv4.)

(For operation when other QoS classifiers apply to the same traffic, refer to “Classifiers for Prioritizing Outbound Packets” on page 8-10.)

Options for Assigning Priority From a RADIUS Server. You can use a RADIUS server to impose a QoS source-port priority during an 802.1X port-access authentication session. Refer to the RADIUS chapter in the Access Security Guide for your switch (January 2005 or later).

Assigning a Priority Based on Source-Port

This option assigns a priority to all outbound packets having the specified source-port. You can configure this option by either specifying the source-port ahead of the qos command or moving to the port context for the port you want to configure for priority. (If you are configuring multiple source-ports with the same priority, you may find it easier to use the interface < port-list> command to go to the port context instead of individually configuring the priority for each port.)

Syntax:  interface < port-list> qos priority < 0 - 7>

Configures an 802.1p priority for packets entering the switch through the specified (source) ports. This priority determines the packet queue in the outbound port(s) to which traffic is sent. If a packet leaves the switch on a tagged port, it carries the 802.1p priority with it to the next downstream device. You can configure one QoS classifier for each source-port or group of source-ports. (Default: No-override)
Quality of Service (QoS): Managing Bandwidth More Effectively
Using QoS Classifiers To Configure Quality of Service for Outbound Traffic

**Syntax:** no interface < port-list > qos

*Disables use of the specified source-port(s) for QoS classifier(s) and resets the priority for the specified source-port(s) to No-override.*

**Syntax:** show qos port-priority

*Lists the QoS port-priority classifiers with their priority data.*

For example, suppose that you want to prioritize inbound traffic on the following source-ports:

<table>
<thead>
<tr>
<th>Source-Port</th>
<th>Priority</th>
</tr>
</thead>
<tbody>
<tr>
<td>A1 - A3</td>
<td>2</td>
</tr>
<tr>
<td>A4</td>
<td>3</td>
</tr>
<tr>
<td>B1, B4</td>
<td>5</td>
</tr>
<tr>
<td>C1-C3</td>
<td>6</td>
</tr>
</tbody>
</table>

You would then execute the following commands to prioritize traffic received on the above ports:

```
ProCurve(config)# interface e c1-c3 qos priority 6
ProCurve(config)# interface e b1,b4 qos priority 5
ProCurve(config)# interface e a4 qos priority 3
ProCurve(config)# interface e a1-a3 qos priority 2
ProCurve(config)# show qos port-priority
```

![Figure 8-31. Configuring and Displaying Source-Port QoS Priorities](image-url)
If you then decided to remove port A1 from QoS prioritization:

```
ProCurve(config)# no interface e a1 qos
ProCurve(config)# show qos port-priority
```

<table>
<thead>
<tr>
<th>Port</th>
<th>Apply rule</th>
<th>DSCP</th>
<th>Priority</th>
<th>Radius Override</th>
</tr>
</thead>
<tbody>
<tr>
<td>A1</td>
<td>No-override</td>
<td>1</td>
<td>No-override</td>
<td>No-override</td>
</tr>
<tr>
<td>A2</td>
<td>Priority</td>
<td>2</td>
<td>No-override</td>
<td>No-override</td>
</tr>
<tr>
<td>A3</td>
<td>Priority</td>
<td>2</td>
<td>No-override</td>
<td>No-override</td>
</tr>
<tr>
<td>A4</td>
<td>Priority</td>
<td>3</td>
<td>No-override</td>
<td>No-override</td>
</tr>
</tbody>
</table>

In this instance, **No-override** indicates that port A1 is not prioritized by QoS.

![Figure 8-32. Returning a QoS-Prioritized VLAN to “No-override” Status](image)

Assigning a DSCP Policy Based on the Source-Port

This option assigns a previously configured DSCP policy (codepoint and 802.1p priority) to outbound IP packets (received from the specified source-ports). That is, the switch:

1. Selects an incoming IP packet on the basis of its source-port on the switch.
2. Overwrites the packet’s DSCP with the DSCP configured in the switch for such packets.
3. Assigns the 802.1p priority configured in the switch for the new DSCP. (Refer to “Differentiated Services Codepoint (DSCP) Mapping” on page 8-64.)
4. Forwards the packet through the appropriate outbound port queue.

**3400cl/6400cl Switch Restriction.** On the 3400cl/6400cl switches, “mixing” ToS DSCP policies and 802.1p priorities is not recommended. Refer to the Note on page 8-11.

For more on DSCP, refer to “Terminology” on page 8-6.

**Steps for Creating a Policy Based on Source-Port Classifiers.**

**Note**

You can select one DSCP per source-port. Also, configuring a new DSCP for a source-port automatically overwrites (replaces) any previous DSCP or 802.1p priority configuration for that port.

1. Identify the source-port classifier to which you want to assign a DSCP policy.
2. Determine the DSCP policy for packets having the selected source-port:
   a. Determine the DSCP you want to assign to the selected packets. (This codepoint will be used to overwrite the DSCP carried in packets received through the source-port from upstream devices.)
   b. Determine the 802.1p priority you want to assign to the DSCP.

3. Configure the DSCP policy by using **qos dscp-map** to configure the priority for each codepoint. (For details, refer to the example later in this section and to “Differentiated Services Codepoint (DSCP) Mapping” on page 8-64.)

**Note**

A codepoint must have an 802.1p priority assignment (0 - 7) before you can configure that codepoint as a criteria for prioritizing packets by source-port. If a codepoint shows **No-override** in the Priority column of the DSCP Policy Table (**show qos dscp-map**), then you must assign a 0 - 7 priority before proceeding.

4. Configure the switch to assign the DSCP policy to packets from the specified source-port.

**Syntax:**  
\[qos\ dscp-map\ <\ codepoint>\ priority\ <0\ -\ 7>\]

This command is optional if a priority has already been assigned to the \(<\ codepoint>\). The command creates a DSCP policy by assigning an 802.1p priority to a specific DSCP. When the switch applies this priority to a packet, the priority determines the packet’s queue in the outbound port to which it is sent. If the packet leaves the switch on a tagged port, it carries the 802.1p priority with it to the next downstream device. (Default: For most codepoints, **No-override**. See figure 8-14 on page 8-64 on page 8-65.)

**Syntax:**  
\[interface\ <\ port-list>\ qos\ dscp\ <\ codepoint>\]

Assigns a DSCP policy to packets from the specified source-port(s), and overwrites the DSCP in these packets with the assigned \(<\ codepoint>\) value. This policy includes an 802.1p priority and determines the packet’s queue in the outbound port to which it is sent. If the packet leaves the switch on a tagged port, it carries the 802.1p priority with it to the next downstream device. (Default: **No-override**)
Quality of Service (QoS): Managing Bandwidth More Effectively
Using QoS Classifiers To Configure Quality of Service for Outbound Traffic

**Syntax:** no interface [e] < port-list > qos

Removes QoS classifier for the specified source-port(s).

**Syntax:** show qos source-port

Displays a listing of all source-port QoS classifiers currently in the running-config file.

For example, suppose you wanted to assign this set of priorities:

<table>
<thead>
<tr>
<th>Source-Port</th>
<th>DSCP</th>
<th>Priority</th>
</tr>
</thead>
<tbody>
<tr>
<td>A2</td>
<td>000111</td>
<td>7</td>
</tr>
<tr>
<td>B1-B3</td>
<td>000101</td>
<td>5</td>
</tr>
<tr>
<td>B4, C2</td>
<td>000010</td>
<td>1</td>
</tr>
</tbody>
</table>

1. Determine whether the DSCP's already have priority assignments, which could indicate use by existing applications. This is not a problem as long as the configured priorities are acceptable for all applications using the same DSCP. (Refer to the “Note On Changing a Priority Setting” on page 8-67. Also, a DSCP must have a priority configured before you can assign any QoS classifiers to use it.)

ProCurve(config)# show qos dscp-map

DSCP -> 802.p priority mappings
DSCP policy 802.1p tag  Policy name

<table>
<thead>
<tr>
<th>DSCP</th>
<th>Policy name</th>
</tr>
</thead>
<tbody>
<tr>
<td>000000</td>
<td>No-override</td>
</tr>
<tr>
<td>000001</td>
<td>No-override</td>
</tr>
<tr>
<td>000010</td>
<td>No-override</td>
</tr>
<tr>
<td>000011</td>
<td>No-override</td>
</tr>
<tr>
<td>000100</td>
<td>No-override</td>
</tr>
<tr>
<td>000101</td>
<td>No-override</td>
</tr>
<tr>
<td>000110</td>
<td>No-override</td>
</tr>
<tr>
<td>000111</td>
<td>No-override</td>
</tr>
</tbody>
</table>

The DSCP's for this example have not yet been assigned an 802.1p priority level.

**Figure 8-33.** Display the Current Configuration in the DSCP Policy Table
Quality of Service (QoS): Managing Bandwidth More Effectively
Using QoS Classifiers To Configure Quality of Service for Outbound Traffic

2. Configure the priorities for the DSCPs you want to use.

![Figure 8-34. Assign Priorities to the Selected DSCPs](image)

3. Assign the DSCP policies to the selected source-ports and display the result.

![Figure 8-35. The Completed Source-Port DSCP-Priority Configuration](image)
Quality of Service (QoS): Managing Bandwidth More Effectively
Using QoS Classifiers To Configure Quality of Service for Outbound Traffic

**Radius Override Field.** During a client session authenticated by a RADIUS server, the server can impose a port priority that applies only to that client session. Refer to the RADIUS chapter in the *Access Security Guide* for your switch (January 2005 or later).

**Differentiated Services Codepoint (DSCP) Mapping**

The DSCP Policy Table associates an 802.1p priority with a specific ToS byte codepoint in an IPv4 packet. This enables you to set a LAN policy that operates independently of 802.1Q VLAN-tagging.

In the default state, most of the 64 codepoints do not assign an 802.1p priority, as indicated by **No-override** in table 8-14 on page 8-65.

You can use the following command to list the current DSCP Policy table, change the codepoint priority assignments, and assign optional names to the codepoints.

**Syntax:**

```
show qos dscp-map
```

*Displays the DSCP Policy Table.*

```
qos dscp-map < codepoint > priority < 0 - 7 > [name < ascii-string >]
```

*Configures an 802.1p priority for the specified codepoint and, optionally, an identifying (policy) name.*

```
no qos dscp-map < codepoint >
```

*Reconfigures the 802.1p priority for <codepoint> to No-override. Also deletes the codepoint policy name, if configured.*

```
no qos dscp-map < codepoint > name
```

*Deletes only the policy name, if configured, for <codepoint>.*

*Assured Forwarding codepoints; configured by default on the Series 5304xl switches. These codepoints are configured as “No-override” in the Series 3400cl, Series 6400cl and Series 2600/2800 switches.

**Expedited Forwarding codepoint configured by default.

Default Priority Settings for Selected Codepoints

In a few cases, such as 001010 and 001100, a default policy (implied by the DSCP standards for Assured-Forwarding and Expedited-Forwarding) is used. You can change the priorities for the default policies by using `qos dscp-map < codepoint> priority < 0 - 7>`.(These policies are not in effect unless you have either applied the policies to a QoS classifier or configured QoS Type-of-Service to be in `diff-services` mode.)
Quickly Listing Non-Default Codepoint Settings

Table 8-14 lists the switch’s default codepoint/priority settings. If you change the priority of any codepoint setting to a non-default value and then execute `write memory`, the switch will list the non-default setting in the show config display. For example, in the default configuration, the following codepoint settings are true:

<table>
<thead>
<tr>
<th>Codepoint</th>
<th>Default Priority</th>
</tr>
</thead>
<tbody>
<tr>
<td>001100</td>
<td>1</td>
</tr>
<tr>
<td>001101</td>
<td>No-override</td>
</tr>
<tr>
<td>001110</td>
<td>2</td>
</tr>
</tbody>
</table>

If you change all three settings to a priority of 3, and then execute `write memory`, the switch will reflect these changes in the show config listing:

```
ProCurve(config)# qos dscp-map 001100 priority 3
ProCurve(config)# qos dscp-map 001101 priority 3
ProCurve(config)# qos dscp-map 001110 priority 3
ProCurve(config)# write memory
ProCurve(config)# show config
Startup configuration:
; J4850A Configuration Editor; Created on release #E.05.01
hostname "HPswitch"
time daylight-time-rule None
cdp run
qos dscp-map 001100 priority 3
gos dscp-map 001101 priority 3
gos dscp-map 001110 priority 3
module 2 type J4821A
module 3 type J4820A
; ; ; ; ;
; ; ; ; ;
```

*Figure 8-36. Example of Show Config Listing with Non-Default Priority Settings in the DSCP Table*

**Effect of “No-override”**. In the QoS Type-of-Service differentiated services mode, a **No-override** assignment for the codepoint of an outbound packet means that QoS is effectively disabled for such packets. That is, QoS does not
affect the packet queuing priority or VLAN tagging. In this case, the packets are handled as follows (as long as no other QoS feature creates priority assignments for them):

<table>
<thead>
<tr>
<th>802.1Q Status</th>
<th>Outbound 802.1p Priority</th>
</tr>
</thead>
<tbody>
<tr>
<td>Received and Forwarded on a tagged port member of a VLAN.</td>
<td>Unchanged</td>
</tr>
<tr>
<td>Received on an Untagged port member of a VLAN; Forwarded on a tagged port member of a VLAN.</td>
<td>0 (zero)—“normal”</td>
</tr>
<tr>
<td>Forwarded on an Untagged port member of a VLAN.</td>
<td>None</td>
</tr>
</tbody>
</table>

### Note On Changing a Priority Setting

If a QoS classifier is using a policy (codepoint and associated priority) in the DSCP Policy table, you must delete or change this usage before you can change the priority setting on the codepoint. Otherwise the switch blocks the change and displays this message:

*Cannot modify DSCP Policy `<codepoint>` - in use by other qos rules.*

In this case, use `show qos <classifier>` to identify the specific classifiers using the policy you want to change; that is:

- `show qos device-priority`
- `show qos port-priority`
- `show qos tcp-udp-port-priority`
- `show qos vlan-priority`
- `show qos type-of-service`

Note that protocol-priority is not included because a DSCP policy is not meaningful for this classifier and therefore not configurable in this case.

For example, suppose that the 000001 codepoint has a priority of 6, and several classifiers use the 000001 codepoint to assign a priority to their respective types of traffic. If you wanted to change the priority of codepoint 000001 you would do the following:

1. Identify which QoS classifiers use the codepoint.
2. Change the classifier configurations by assigning them to a different DSCP policy, or to an 802.1p priority, or to **No-override**.
3. Reconfigure the desired priority for the 000001 codepoint.
4. Either reassign the classifiers to the 00001 codepoint policy or leave them as they were after step 2, above.
Example of Changing the Priority Setting on a Policy When One or More Classifiers Are Currently Using the Policy

Suppose that codepoint 000001 is in use by one or more classifiers. If you try to change its priority, you see a result similar to the following:

```
ProCurve(config)# qos dscp-map 000001 priority 2
Cannot modify DSCP Policy 000001 – in use by other qos rules.
```

Figure 8-37. Example of Trying To Change the Priority on a Policy In Use by a Classifier

In this case, you would use steps similar to the following to change the priority.

1. Identify which classifiers use the codepoint you want to change.
Quality of Service (QoS): Managing Bandwidth More Effectively
Using QoS Classifiers To Configure Quality of Service for Outbound Traffic

Three classifiers use the codepoint that is to be changed.

ProCurve(config)# show qos device-priority

Device priorities
Device Address  Apply rule | DSCP | Priority
---------------------- --------- --------
10.26.50.104         DSCP     | 000001 | 6

ProCurve(config)# show qos port-priority

Port priorities
Port Apply rule | DSCP | Priority | Radius Override
--- ----------- | ----- | -------- | ------------------
A1 No-override | No-override | No-override
A2 No-override | No-override | No-override
A3 DSCP       | 000001 | 6        | No-override
A4 No-override | No-override | No-override
A5 No-override | No-override | No-override

ProCurve(config)# show qos tcp-udp-port-priority

TCP/UDP port based priorities
Protocol | Application Port Apply rule | DSCP | Priority
--------- + --------------------- --------- --------
UDP      | 1260                  DSCP     | 000001 | 6

ProCurve(config)# show qos vlan-priority

VLAN priorities
VLAN ID  Apply rule | DSCP | Priority
--------- ----------- | ----- | --------
1         No-override | No-override

ProCurve(config)# show qos type-of-service

Type of Service [Disabled] : (Disabled)

Figure 8-38. Example of a Search to Identify Classifiers Using a Codepoint You Want To Change
2. Change the classifier configurations by assigning them to a different DSCP policy, or to an 802.1p priority, or to **No-override**. For example:
   a. Delete the policy assignment for the **device-priority** classifier. (That is, assign it to **No-override**.)
   b. Create a new DSCP policy to use for re-assigning the remaining classifiers.
   c. Assign the **port-priority** classifier to the new DSCP policy.
   d. Assign the **udp-port 1260** classifier to an 802.1p priority.

   ```
   a) ProCurve(config)# no qos device-priority 10.26.50.104
   b) ProCurve(config)# qos dscp-map 000100 priority 6
   c) ProCurve(config)# int e a3 qos dscp 000100
   d) ProCurve(config)# qos udp-port 1260 priority 2
   ```

3. Reconfigure the desired priority for the 000001 codepoint.
   ```
   ProCurve(config)# qos dscp-map 000001 priority 4
   ```

4. You could now re-assign the classifiers to the original policy codepoint or leave them as currently configured.
IP Multicast (IGMP) Interaction with QoS

IGMP high-priority-forward causes the switch to service the subscribed IP multicast group traffic at high priority, even if QoS on the switch has relegated the traffic to a lower priority. This does not affect any QoS priority settings, so the QoS priority is honored by downstream devices. However, QoS does take precedence over IGMP normal-priority traffic.

The switch’s ability to prioritize IGMP traffic for either a normal or high priority outbound queue overrides any QoS criteria, and does not affect any 802.1p priority settings the switch may assign. For a given packet, if both IGMP high priority and QoS are configured, the QoS classification occurs and the switch marks the packet for downstream devices, but the packet is serviced by the high-priority queue when leaving the switch.

<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>DSCP Policy <code>&lt;decimal-codepoint&gt;</code> not configured</td>
<td>You have attempted to map a QoS classifier to a codepoint for which there is no configured priority (<code>No-override</code>). Use the <code>qos dscp-map</code> command to configure a priority for the codepoint, then map the classifier to the codepoint.</td>
</tr>
<tr>
<td>Cannot modify DSCP Policy <code>&lt;codepoint&gt;</code> - in use by other qos rules.</td>
<td>You have attempted to map a QoS classifier to a codepoint that is already in use by other QoS classifiers. Before remapping the codepoint to a new priority, you must reconfigure the other QoS classifiers so that they do not use this codepoint. You can have multiple QoS classifiers use this same codepoint as long as it is acceptable for all such classifiers to use the same priority.</td>
</tr>
</tbody>
</table>

\(^1\) An “IP Option” is an optional, extra field in the header of an IP packet. If a 3400cl or 6400cl switch is configured with a UDP/TCP classifier and a packet with an IP option is received, the switch uses the next-highest classifier that is configured and applicable to actually match and classify the packet.

\(^2\) All Switches: For explicit QoS support of IPv6 packets, force IPv6 traffic into its own set of VLANs and then configure VLAN-based classifiers for those VLANs.

\(^3\) On IPv4 packets with IP options, the 5300xl and 4200vI switches support QoS for 802.1p priority policies, but does not do any DSCP re-marking for DSCP policies.

- **All Switches:** For explicit QoS support of IP subnets, HP recommends forcing IP subnets onto separate VLANs and then configuring VLAN-based classifiers for those VLANs.

- **For Devices that Do Not Support 802.1Q VLAN-Tagged Ports:** For communication between these devices and the switch, connect the device to a switch port configured as **Untagged** for the VLAN in which you want the device’s traffic to move.

- **Port Tagging Rules:** For a port on the switch to be a member of a VLAN, the port must be configured as either **Tagged** or **Untagged** for that VLAN. A port can be an untagged member of only one VLAN of a given protocol type. Otherwise, the switch cannot determine which
VLAN should receive untagged traffic. For more on VLANs, refer to chapter 2, “Static Virtual LANs (VLANs)

- **3400cl and 6400cl Switches Only—SAP-Encapsulated Packet Restriction:** Except for source-port QoS and VLAN QoS, the 3400cl/6400cl switches do not support QoS (or ACL) operation for SAP-Encapsulated packets.

- **3400cl/6400cl Switches Only—Packets with IP Option Fields in the Header:** UDP/TCP QoS is not supported for IP packets carrying optional fields in their headers.

- **Maximum QoS Configuration Entries:** The switches covered by this guide accept the maximum outbound priority and/or DSCP policy configuration entries shown in table 8-16.

### Table 8-16. Maximum QoS Entries.

<table>
<thead>
<tr>
<th>Switch</th>
<th>Software Version</th>
<th>Maximum QoS Entries</th>
<th>Notes for All Switch Models</th>
</tr>
</thead>
<tbody>
<tr>
<td>Series 5300xl E.08.01 and greater</td>
<td>250*</td>
<td>• Each device (IP address) QoS configuration uses two entries.</td>
<td></td>
</tr>
<tr>
<td>Series 3400cl and Series 6400cl</td>
<td>120*</td>
<td>• Each TCP/UDP port QoS configuration uses four entries.</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>• All other classifier configurations use one entry each.</td>
<td></td>
</tr>
</tbody>
</table>

*Configuring device (IP address) or TCP/UDP QoS entries reduces this maximum. See the “Notes” column.

Attempting to exceed the above limits generates the following message in the CLI:

Unable to add this QoS rule. Maximum number (entry-#) already reached.

**5300xl and 4200vl:** Where a 5300xl switch is running a software release earlier than E.08.01 and is configured with more than 250 QoS rules, downloading software release E.08.01 (or greater) causes the switch to:

- Implement the first 250 QoS rules in its configuration, but ignore the configured rules exceeding that limit.

- Generate these Event Log messages:
  - Too many QoS configuration items - limit of 250
  - Some QoS configuration items will not be active
Quality of Service (QoS): Managing Bandwidth More Effectively
QoS Operating Notes and Restrictions

- **5300xl and 4200vl Switches—Non-Supported IP Packets:** The DSCP policy codepoint-remarking operation is not supported in any QoS classifier for packets carrying IP options in the packet header.

- **All Switches—Not Supported:** Use of an inbound 802.1p packet priority as a classifier for remapping a packet’s outbound priority to different 802.1p priority. For example, where inbound packets carry an 802.1p priority of 1, QoS cannot be configured use this priority as a classifier for changing the outbound priority to 0.
